ON ELIMINATION OF VARIABLES IN THE STUDY OF SINGULARITIES IN
POSITIVE CHARACTERISTIC

ANGÉLICA BENITO AND ORLANDO E. VILLAMAYOR U.

Abstract. The objective of this paper is to discuss some invariants of singularities of algebraic schemes over fields of positive characteristic, and to show their usefulness for the simplification of singularities. We focus here on invariants which arise in an inductive manner, namely by successive elimination of variables. When applied to a hypersurface singularity, they lead to a refinement of the notion of multiplicity. Note that the Weierstrass Preparation Theorem allows us to express the equation defining the hypersurface as a polynomial equation. In this case the new invariants can be defined, in some way, from the coefficients of this polynomial, and hence this theorem enables us to define invariants in one variable less.

In this paper we present a generalized form of the Weierstrass Preparation Theorem which enables us to eliminate several variables at once, and to define invariants in this more general setting.

This leads to the definition of inductive invariants which refine the multiplicity in the hypersurface case. In addition, they provide a refinement of the Hilbert-Samuel stratification for the non-hypersurface case.

The paper includes some applications of these invariants to the open problem of resolution of singularities.

1. Introduction

1.1. In 1964 Hironaka proves resolution of singularities over fields of characteristic zero in his celebrated paper [27]. He firstly quantifies the singularities making use of the Hilbert-Samuel function. More precisely, a singular variety \( X \) is stratified in accordance to the Hilbert-Samuel function attached to its points. Roughly speaking, each stratum is given by the points that have the same function.

He proves that this invariant (the worst Hilbert-Samuel function corresponding to points in \( X \)) can be improved by applying suitable transformations, and that resolution of singularities is achieved by successive applications of this procedure.
The significant step in his proof consists in proving that the worst Hilbert-Samuel function can be improved. To this end he makes use of local arguments, and assumes that locally at a given point \( x \in X \) there is an immersion \( X \subset W \), where \( W \) is a regular variety. If \( I \) denotes the ideal defining \( X \) at \( O_{W,x} \) he constructs, at the completion \( \hat{O}_{W,x} \), finitely many elements \( \{h_1, \ldots, h_s\} \) and positive integers \( \{n_1, \ldots, n_s\} \), so that each \( h_i \) has multiplicity \( n_i \) at \( \hat{O}_{W,x} \), and the completion of the Hilbert-Samuel stratum is given by

\[
\mathcal{H} = \bigcap \{w \in W' \mid \text{ord}_w(h_i) \geq n_i\},
\]

where \( W' = \text{Spec}(\hat{O}_{W,x}) \). In particular, a regular center \( Y \) is locally included in the Hilbert-Samuel stratum of \( X \subset W \), if and only if its pull-back at \( W' \), say \( Y' \), is an equimultiple center for each hypersurface defined by \( h_1 = 0 \). He shows that the so called idealistic exponent, say \( \{h_1, \ldots, h_s\} \) and \( \{n_1, \ldots, n_s\} \), can be chosen so that \( \{h^{(1)}_1, \ldots, h^{(1)}_s\} \) denote the strict transforms at \( W'^{(1)} \), obtained by blowing up \( Y' \), then the pullback to \( W'^{(1)} \) of the Hilbert stratum of the strict transform of \( X \) is defined by

\[
\mathcal{H}'^{(1)} = \bigcap \{w \in W'^{(1)} \mid \text{ord}_w(h^{(1)}_i) \geq n_i\}.
\]

In addition, he shows that \( \{h_1, \ldots, h_s\} \) and \( \{n_1, \ldots, n_s\} \) can be chosen so that this condition holds after applying any sequence of blow ups at centers included in the Hilbert-Samuel stratum.

This provides a local reduction to the hypersurface case, and the advantage is that the law of transformation of a hypersurface is easy to handle.

A resolution of an idealistic exponent consists on the construction of a sequence of monoidal transformations so that the final transform, say \( \mathcal{H}^{(r)} \),

\[
\mathcal{H}^{(r)} = \bigcap \{w \in W'^{(r)} \mid \text{ord}_w(h^{(r)}_i) \geq n_i\}
\]

is empty. This would lead to an improvement of the worst Hilbert-Samuel stratum, at least locally above \( x \in X \).

In addition, Hironaka assigns to an idealistic exponent the notion of maximal contact, consisting in part of a regular system of parameters of \( \hat{O}_{W,x} \), say \( \{z_1, \ldots, z_r\} \), which is obtained from the data. The regular variety \( \{z_1 = 0, \ldots, z_r = 0\} \) has the property that it contains the Hilbert-Samuel stratum \( \mathcal{H} \), say

\[
\mathcal{H} \subseteq \{z_1 = 0, \ldots, z_r = 0\} = \bigcap \{w \in W' \mid \text{ord}_w(z_i) \geq 1\},
\]

and that the inclusion is preserved by the previous kind of monoidal transformations.

This inclusion is crucial in Hironaka’s induction on the dimension of the ambient space, it enables him to construct a resolution of an idealistic exponent.

Let us indicate that this construction of the idealistic exponents at the completion, and of their resolution at this setting, were sufficient to obtain the non-constructive proof presented in [27].

In 1975, in [22], Giraud partially extends the previous results to the case of positive characteristic: Given a point \( x \in X \), and an immersion \( X \subset W \) in a regular variety, he constructs at \( \hat{O}_{W,x} \) a presentation (see [22] Definition 3.1):

- an idealistic exponent given by elements \( h_1, \ldots, h_s \) and integers \( n_1, \ldots, n_s \), such that each \( h_i \) has multiplicity \( n_i \) at \( \hat{O}_{W,x} \), and the Hilbert-Samuel stratum is

\[
\mathcal{H} = \bigcap \{w \in W' \mid \text{ord}_w(h_i) \geq n_i\},
\]

where, again, \( W' = \text{Spec}(\hat{O}_{W,x}) \),

- a part of a regular system of parameters \( \{z_1, \ldots, z_r\} \) of \( \hat{O}_{W,x} \),

- elements \( f_1, \ldots, f_r \) of order \( p^\infty \), certain powers of the characteristic, such that, if the base field is perfect, then \( \text{In}_x(f_i) = Z_i^{p^{\nu_i}} \in \text{gr}(\hat{O}_{W,x}) \), where \( Z_i = \text{In}_x(z_i) \).
In this setting the polynomials \( f_j \) mimic the role of the maximal contact given by Hironaka since the pullback of the Hilbert-Samuel stratum fulfills

\[
\mathcal{H} \subseteq \bigcap \{ w \in W' \mid \text{ord}_w(f_i) \geq p^{\tau_i} \}.
\]

Moreover, if \( Y \) is a regular subvariety included in the Hilbert-Samuel stratum, and \( Y' \) is as before, Giraud proves that the previous inclusion is stable under a blow-up along \( Y' \), say

\[
\mathcal{H}^{(1)} \subseteq \bigcap \{ w \in W'^{(1)} \mid \text{ord}_w(f_i^{(1)}) \geq p^{\tau_i} \},
\]

where the \( f_i^{(1)} \) are the strict transforms of the \( f_i \) at \( W'^{(1)} \).

Let us indicate that the previous elements \( z_1, \ldots, z_s \) are given with prescribed properties: the initial forms \( Z_i = \text{In}_w(z_i) \) describe the ridge of the tangent cone, which is a subspace included in \( T_{X,x} \). In addition, Giraud adds to this data a formally smooth morphism from \( W' \) to a formally smooth scheme of dimension \( d - \tau \). This morphism is in some natural way transversal to the idealistic exponent, and this transversality is preserved by blow-ups that are defined as above.

In 1977, Hironaka shows that \( \{h_1, \ldots, h_s\} \) and \( \{n_1, \ldots, n_s\} \) can be constructed, within the conditions introduced by Giraud, but now at the henselization of \( O_{W,x} \) (see \[31\]). This is a result of Aroca that applies to varieties defined over perfect fields, and allows to show that all the previous data hold at a suitable étale neighborhood of \( x \in W \). Therefore Giraud’s presentations can be developed within the class of schemes of finite type over a perfect field.

The results in this paper are related in many ways to those of Giraud, although we also make use of the existence of idealistic exponents in étale topology. Our motivation is Hironaka’s treatment of idealistic exponents in characteristic zero. In this case, he constructs a maximal contact variety of dimension \( d - \tau \). Moreover he defines a new idealistic exponent in this smaller dimensional regular variety. It is in terms of these restricted data, that he defines a function, called here H-ord\((d-\tau)\) (see \[31\] Proposition 8). We also refer to Theorem 11.1 and Definition 11.8 in \[33\] for Hironaka’s definition of these functions in the context of local analytic spaces.

In this paper, we reproduce, at least partially, this strategy in characteristic \( p \), with some essential differences: we make use, as in Giraud’s approach, of suitable transversal projections from a regular variety of dimension \( d \) to one of dimension \( d - \tau \), together with a form of elimination of variables. A second ingredient, also crucial for the construction of our extended function H-ord\((d-\tau)\), will be the Generalized Preparation Theorem (see Theorem \[48\]). This Theorem will encompass all the data in Giraud’s presentations, and allows us to improve the form of Giraud’s functions \( f_i \).

In fact, the transversal projection and the preparation theorem enable us to present the \( f_i \) as polynomials. Moreover, the \( f_i \) are of the form:

\[
f_i(z_i) = z_i^{p^{\tau_i}} + a_1^{(i)} z_i^{p^{\tau_i}-1} + \cdots + a_{p^{\tau_i}},
\]

where the \( a_j^{(i)} \) now involve only \( d - \tau \)-variables, and \( \text{In}_w(z_i) = Z_i, \ 1 \leq i \leq \tau \), define the ridge of the tangent cone at the given point. We will show that the presentations given in this form are also stable under monoidal transformations.

So, in our approach, the notion of restriction is replaced by that of projections. This is done in such a way that, when specialized to characteristic zero, we recover Hironaka’s original H-ord\((d-\tau)\) function.

As indicated, the invariants to be introduced here will be obtained by successive elimination of variables. They will generalize, at least for the case of elimination of one variable, invariants that were already treated in pioneering works of Cossart and Moh. This will also provide a refinement of the Hilbert-Samuel stratification for a scheme of finite type over a perfect field.

Finally, in Section \[7\] some numerical conditions, involving these invariants, will be discussed. We will ultimately show that, when these conditions hold, the worst Hilbert-Samuel stratum can be
simplified by means of permissible transformations (blow-ups along centers included in a Hilbert-Samuel stratum).

1.2. The form of elimination to be considered makes use of the Weierstrass Preparation Theorem: Fix a closed point \( x \in X \), where \( X \) denotes a hypersurface embedded in a smooth \( d \)-dimensional ambient scheme over a perfect field \( k \), say \( V^{(d)} \). Let the multiplicity of \( X \) at \( x \) be \( n \). The Weierstrass Preparation Theorem asserts that, at a suitable étale neighborhood of \( V^{(d)} \) at \( x \), one can define a smooth morphism, say \( V^{(d)} \xrightarrow{\beta} V^{(d-1)} \), so that the ideal of the hypersurface \( X \) is spanned by a monic polynomial, say

\[
f(z_1) = z_1^n + a_1 z_1^{n-1} + \cdots + a_n \in \mathcal{O}_{V^{(d-1)}}[z_1].
\]

Here \( \{z_1 = 0\} \) is a section of \( \beta \), the coefficients lie in the smooth scheme \( V^{(d-1)} \), and \( \{z_1\} \) can be extended to a regular system of parameters in \( \mathcal{O}_{V^{(d)},x} \). These coefficients involve one variable less, so there is a form of elimination of \( z_1 \) in this approach. Despite the fact that such polynomial is not intrinsic to \( x \in X \), there is significant information of the singularity encoded in the coefficients, used here to define some \textit{invariants} of the singularity \((X, x)\).

The \( \tau \)-invariant at a point \( x \in X \), defined in terms of the ridge of the tangent cone, is a positive integer that indicates the number of variables that can be naturally eliminated, at least for the purpose of simplifying the singularity. We present a generalized form of the Weierstrass Preparation Theorem, which fits better in this frame, in which \( \tau \) variables are to be eliminated \((\tau \geq 1)\). To illustrate this fact, assume that \( \tau \geq 2 \), in this case this invariant indicates that one can eliminate two variables simultaneously. The usual Weierstrass Preparation Theorem would provide a smooth morphism, at an étale neighborhood of \( x \), say \( V^{(d)} \xrightarrow{\beta} V^{(d-1)} \), together with two monic polynomials,

\[
f_1(z_1) = z_1^n + a_1 z_1^{n-1} + \cdots + a_n \in \mathcal{O}_{V^{(d-1)}}[z_1], \quad \text{and} \quad f_2(z_2) = z_2^m + b_1 z_2^{m-1} + \cdots + b_m \in \mathcal{O}_{V^{(d-1)}}[z_2].
\]

The draw-back of this outcome is that the coefficients of both polynomials lie in \( V^{(d-1)} \), whereas we would like to eliminate simultaneously the two variables \( z_1 \) and \( z_2 \). We circumvent this difficulty by presenting a suitable generalization of the Weierstrass Preparation Theorem, which enable us to construct a smooth morphism, say \( V^{(d)} \xrightarrow{\beta} V^{(d-2)} \), defined at an étale neighborhood of \( x \), so that the ideal of the two equations can be expressed by monic polynomials of the form

\[
f_1(z_1) = z_1^n + a_1 z_1^{n-1} + \cdots + a_n \in \mathcal{O}_{V^{(d-2)}}[z_1], \quad \text{and} \quad f_2(z_2) = z_2^m + b_1 z_2^{m-1} + \cdots + b_m \in \mathcal{O}_{V^{(d-2)}}[z_2].
\]

Here \( z_1 \) and \( z_2 \) can be chosen so that \( z_1 = 0 \) and \( z_2 = 0 \) are two different sections of \( \beta \), and \( \{z_1, z_2\} \) can be extended to a regular system of parameters in \( \mathcal{O}_{V^{(d)},x} \) (see Proposition 6.3).

The advantage of this new formulation over the previous one is that the coefficients of both polynomials lie in a smooth scheme of dimension \( d - 2 \) (involving two variables less).

Moreover, when Hironaka’s invariant is \( r \), the generalized Weierstrass Preparation Theorem (Theorem 6.5) allows us to find \( r \) monic polynomials, all with coefficients in a smooth scheme of dimension \( d - r \) (involving \( r \) variables less).

Some applications of this form of the Preparation Theorem will be addressed in the last part of Section 6 and Section 7. There we extend the main results in [6], in particular, the definition of the \( H \)-functions (see Definition 6.13), treated in the cited paper for the case \( \tau = 1 \).

These \( H \)-functions will be used to formulate the notion of \textit{strong monomial case} (Definition 7.4), and also to show that the simplification of singularities is possible in such case (see Theorem 7.6). The latter is a natural extension of [6] Theorem 8.14.

Another application of the generalized Preparation Theorem is the resolution of singularities of 2-dimensional schemes (Theorem 7.5) by blowing-up at regular centers. This result is an extension of the resolution of surfaces embedded in 3-dimensional spaces, as was proved in [7].
The notion of invariant, as used in Hironaka’s work, has a very precise meaning and special features. This will be discussed at the beginning of the next sections. These features will also hold for those invariants introduced in this work. In particular, they will inherit properties as that of equivariance.

Let us indicate that the invariants attached to a polynomial at a point in Theorem 4.11 and Corollary [12] are also treated by Cossart-Piltant in [15, Definition 2.15], and studied there in a more general context, including the arithmetic case. We also refer to the work of Kawanoue-Matsuki ([36], [37]) for other invariants attached to singularities in positive characteristic.

Acknowledgements: We would like to thank the referee for some suggestions that have helped us to improve the presentation of this paper. We have profited from discussions with K. Matsuki, A. Bravo, and S. Encinas.

2. Some basics and an overall view of the paper

2.1. Hironaka proved resolution of singularities in characteristic zero in [27]. His proof is existential whereas we are going to discuss here constructive, or say algorithmic, proofs of this theorem.

As a first approach an algorithm of resolution of singularities would be a procedure in which once you fix a variety the result is a unique sequence of transformations, and the final transform of the variety is smooth.

\[
\begin{array}{c}
X \xrightarrow{\text{input}} \text{Algorithm} \xrightarrow{\text{output}} X^{\pi_1} \leftarrow X_1 \leftarrow \ldots \leftarrow X_r.
\end{array}
\]

It is natural to require some properties to this algorithm, for example:

- **Compatibility with isomorphisms**: Fix two schemes \( X \) and \( Y \) and assume that \( \theta : X \rightarrow Y \) is an isomorphism of schemes. Once we fix a smooth subscheme \( C \subset X \), we can consider the blow up along \( C \), say \( X^{\pi_C} \xleftarrow{\theta_1} X_1 \). On the other hand, consider the blow up along \( \theta(C) \), say \( Y^{\pi_{\theta(C)}} \xleftarrow{\theta_1} Y_1 \). This gives rise to a square diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\pi_C} & X_1 \\
\theta \cong & \cong & \theta_1 \\
Y & \xrightarrow{\pi_{\theta(C)}} & Y_1
\end{array}
\]

Having this in mind, it is quite predictable to require the algorithm of resolution to be compatible with isomorphism. Namely that the sequences of transformations assigned by the algorithm to \( Y \) and to \( X \) should be related in this manner (by considering the fiber product).

- **Compatibility with restriction to open subsets**.
- **Compatibility with smooth morphisms**.

The last two properties can be explained in the same way we have described the compatibility with isomorphisms.

These properties are known to hold for constructive resolutions ([44]). There are multiple forms to create an algorithm (and in fact, there are many of them).

The importance of the notion of compatibility with isomorphism was indicated by Hironaka in [31]. However this concept evolves from the theory of Trees, Groves and Polygroves, developed by Hironaka in earlier publications (see for example [30]). These ideas are the starting point for the concept of “invariant” as used by Hironaka. They play a relevant role in the globalization of local data (e.g., [28]). An invariant function will be a function defined in points of a varieties which fulfills the natural properties of the previous discussion, i.e.,
two isomorphic varieties will have the same invariant function. In other words, if $X \xrightarrow{\theta} Y$ is an isomorphism of varieties and $i_X$, $i_Y$ are the correspondent invariant functions, then $i_X(x) = i_Y(\theta(x))$.

- Good behavior with restriction to open sets and with étale topology.

A first example of an invariant function is the Hilbert-Samuel function that we will discuss below.

**Remark 2.2.** An algorithm of resolution of singularities is our first example of invariant function. Despite the fact that Hilbert-Samuel function is an invariant function, it is not enough to prove resolution of singularities, but it will be the first step in the search of an algorithm. In fact algorithms of resolution are given as a suitable refinement of the Hilbert-Samuel function (see [8], [18], [43], [48]).

2.3. Let $X \subset V^{(d)}$ be a hypersurface embedded in a $d$-dimensional smooth scheme over a perfect field $k$. An upper semi-continuous function, say

$$\text{mult} : X \rightarrow \mathbb{Z},$$

is defined by setting $\text{mult}(x)$ as the multiplicity of $X$ at $x$.

If $b \in \mathbb{Z}$ denotes the highest value achieved by this function, then the set of $b$-fold points, say $X(b) = \{x \in X \mid \text{mult}(x) = b\}$, is closed. We encompass this situation in a more general setting which leads us to the notion of *pairs*:

**Pairs:** Set, as before, $V^{(d)}$ a $d$-dimensional smooth scheme over a perfect field $k$. Fix a non-zero sheaf of ideals, say $J \subset \mathcal{O}_{V^{(d)},x}$, and a positive integer $b$. Here $(J,b)$ is called a *pair*. It defines a closed subset in $V^{(d)}$, called the *singular locus* of $(J,b)$, say

$$\text{Sing}(J,b) = \{x \in V^{(d)} \mid \nu_x(J) \geq b\},$$

where $\nu_x(J)$ denotes the order of $J$ in regular local ring $\mathcal{O}_{V^{(d)},x}$. When $J = I(X)$ and $X$ is a hypersurface, the singular locus $\text{Sing}(J,b)$ is the set of $b$-fold points of $X$.

Let $Y$ be a smooth irreducible subscheme included in $\text{Sing}(J,b)$, and let $V^{(d)} \xrightarrow{\pi_Y} V_1^{(d)}$ denote the monoidal transformation with center $Y$. Note that there is a factorization of the form

$$J\mathcal{O}_{V^{(d)}} = I(H)^b J_1,$$

where $H = \pi_Y^{-1}(Y)$ denotes the exceptional hypersurface. This defines a new pair $(J_1,b)$, called the *transform* of $(J,b)$. Similarly, an iteration of transformations, say

$$V^{(d)} \xrightarrow{\pi_Y} V_1^{(d)} \xrightarrow{\pi_{Y_1}} \cdots \xrightarrow{\pi_{Y_r}} V_r^{(d)}$$

(2.3.1)

can be defined by setting $V_i^{(d)} \xrightarrow{\pi_{Y_i}} V_{i+1}^{(d)}$ as the transformation with smooth centers $Y_i \subset \text{Sing}(J_i,b)$. Let $H_{i+1}$ denote the new exceptional hypersurface in $V_{i+1}^{(d)}$.

We shall always assume that such sequences are defined in such a way that the strict transforms of the $r$ exceptional hypersurfaces, say $\{H_1, \ldots, H_r\}$, have normal crossings in $V_r^{(d)}$. A sequence of transformation, as above, is said to be a *resolution* if, in addition, $\text{Sing}(J_r,b) = \emptyset$.

In the case of hypersurfaces, a resolution of the pair $(I(X),b)$ defines an elimination of the $b$-fold points of $X$ by blowing-up centers included in the successive $b$-fold points of the strict transforms of the hypersurface.

Our strategy to define a refinement of the multiplicity will be accomplished in steps. A first approach is to search for functions defined on the class of pairs. Namely functions defined in some prescribed way along the closed sets defined by pairs.

For more general varieties $X \subset V^{(d)}$, one can work with the Hilbert-Samuel function. Consider, at each closed point $\xi \in X$, the graph of the Hilbert-Samuel function at the local ring $\mathcal{O}_{X,\xi}$. This is
a function from $\mathbb{N}$ to $\mathbb{N}$, so the graph is an element of $\mathbb{N}^\mathbb{N}$, which we consider with the lexicographic ordering. It is possible to extend this function to non-closed points, say

$$HS_X : X \rightarrow \mathbb{N}^\mathbb{N},$$

in such a way that it is upper semicontinuous. The stratification on $X$ defined by this function is called the Hilbert-Samuel stratification (each stratum is called a Hilbert-Samuel stratum). Consider $\max HS_X$ to be the maximum value of $HS_X$, and denote by $\text{Max} HS_X$ the maximum stratum of the Hilbert-Samuel function, say $\text{Max} HS_X = \{ \xi \in X \mid HS_X(\xi) = \max HS_X \}$. In the same way as with the multiplicity for a hypersurface discussed before, Hironaka defines a pair $(J, b)$ with the properties:

1. $\text{Max} HS_X = \text{Sing}(J, b)$.
2. Any sequence of transformations of pairs

$$(2.3.2) \quad V^{(d)} \xrightarrow{\pi_r} V_1^{(d)} \xrightarrow{\pi_{r-1}} \cdots \xrightarrow{\pi_1} V_r^{(d)}$$

will induce a sequence of transformations over $X$, say

$$(2.3.3) \quad X \xrightarrow{\pi_r} X_1 \xrightarrow{\pi_{r-1}} \cdots \xrightarrow{\pi_1} X_r$$

and moreover, the equality

$$(2.3.4) \quad \text{Max} HS_{X_i} = \text{Sing}(J_i, b)$$

holds for any index $i < r$.

Note that if $(2.3.2)$ is a resolution of the pair $(J, b)$, namely if $\text{Sing}(J, b) = \emptyset$, then the maximum value of the Hilbert-Samuel function drops at $X_r$ for the induced sequence $(2.3.3)$. So resolution of pairs lead to improvement of the maximum value of $HS_X$, moreover Hironaka proves that resolution of singularities is achieved by iterating this procedure.

**Problem:** We have fixed $X \subset V^{(d)}$ and attached to it a pair $(J, b)$. Assume now that one considers a different embedding of $X$, say $X \subset V'^{(d)}$, with the same dimension $d$. Suppose that there is a new pair $(J', b')$ that fulfills the two previous properties. It is natural to require that the induced transformations defined over $X$, defined by a resolution of $(J, b)$, be the same as that obtained by a resolution of $(J', b')$.

In order to address these questions one defines an algorithm of resolution of basic objects. Namely, we define a totally ordered set $\Gamma$, and, for each pair $(J, b)$, an upper semi-continuous function $\delta_{(J,b)} : \text{Sing}(J, b) \rightarrow \Gamma$, so that the closed stratum corresponding to the biggest value, say $\text{Max} \delta_{(J,b)}$ is regular, and such that a resolution of the pair is achieved by successive blow ups at such stratum.

**Requirement.** The requirement we impose on an algorithm is now clear: Given $X \subset V^{(d)}$ and a pair $(J, b)$, and given $X \subset V'^{(d)}$ and a pair $(J', b')$, both in the previous conditions for the same $X$, we require that the sequence of transformations defined over $X$ by the resolution of $(J, b)$ be the same as that defined by the resolution of $(J', b')$.

Note here that $(2.3.3)$ allows us to define these functions on $\text{Max} HS_{X_i} (= \text{Sing}(J_i, b) = \text{Sing}(J'_i, b'))$. The requirement is fulfilled if the induced functions over $X$ are independent of the pairs $(J, b)$ and $(J', b')$ described before, and if this fact is preserved by the prescribed blow-ups.

A first step in the definition of this algorithm, subject to this requirement, is given by Hironaka’s function.
Remark 2.4. Hironaka defines a function $\text{ord}_{(J,b)} : \text{Sing}(J,b) \rightarrow \mathbb{Q}$, by
\[
\text{ord}_{(J,b)}(\xi) = \frac{\nu_{\xi}(J)}{b},
\]
where $\nu_{\xi}(J)$ is the order of ideal $J$ in the regular local ring $O_{V(d),\xi}$. Recall that $\text{Sing}(J,b) = \text{Max}\ HS_X = \text{Sing}(J',b')$.

A remarkable property of this function, to be discussed below, is that
\[
(2.4.1) \quad \text{ord}_{(J,b)}(\xi) = \text{ord}_{(J',b')}(\xi)
\]
for any $\xi \in \text{Max}\ HS_X$. This fact leads to the definition of the function
\[
\text{ord}_X : \text{Max}\ HS_X \rightarrow \mathbb{Q}.
\]
This key observation ensures that if the algorithm, namely $\Gamma$ and the functions $\delta_{(J,b)} : \text{Sing}(J,b) \rightarrow \Gamma$, are defined in terms of Hironaka’s function, then the requirement is automatically fulfilled.

This is precisely how algorithms of resolution in characteristic zero are defined.

2.5. On the equality (2.4.1) and the property of equivariance.

Definition 2.6. Fix a point $x \in \text{Sing}(J,b)$, a marked sequence over $x$ is given by:

1. sequence of transformations

\[
(2.6.1) \quad V^{(d)} \xrightarrow{\pi_1} V_1^{(d)} \xrightarrow{\pi_2} \ldots \xrightarrow{\pi_{\ell-1}} V_{\ell}^{(d)}
\]

where the centers of the transformation $\pi_j$ is included in $\text{Sing}(J_{j-1},b_j)$, and

2. a collection of points $x_0, \ldots, x_{\ell}$, where

\[
\pi_i(x_j) = x_{i-1} \quad \text{and} \quad x_0 = x.
\]

To be precise in the previous sequence of transformations one can intercalate other morphisms like restrictions to open sets or multiplications by affine spaces. We refer to [5] for more details on this notion.

Remark 2.7. Hironaka’s set theoretical observation The rational number $\text{ord}_{(J,b)}(\xi)$ can be read from the marked sequences over $\xi$. More precisely it is given by $\text{codim}_x_i(\text{Sing}(J_i,b))$ in $V_i^{(d)}$.

Some consequences:

- Note here that any marked sequence over $\xi$ of the form (2.6.1) induces a sequence of embedded transformations over $X$, say

\[
V^{(d)} \xrightarrow{\pi_1} V_1^{(d)} \xrightarrow{\pi_2} \ldots \xrightarrow{\pi_{\ell-1}} V_{\ell}^{(d)}
\]

and a collection of points $x_i \in X_i$, where $\pi_i(x_i) = x_{i-1}$, and $x_0 = \xi$.

The previous observation can be reformulated in such a way that the rational number $\text{ord}_{(J,b)}(\xi)$ is given by $\text{codim}_x_i(\text{Max}\ HS_X)$ in $V_i^{(d)}$. In particular, $\text{ord}_{(J,b)}(\xi) = \text{ord}_{(J',b')}(\xi)$ via the identifications $\text{Sing}(J_i,b) = \text{Max}\ HS_X = \text{Sing}(J'_i,b_i)$.

- Let $\alpha : X \rightarrow Y$ be an isomorphism of schemes. We had the data $X \subset V^{(d)}$, and the pair $(J,b)$. The isomorphism $\alpha$ provides an inclusion $Y \subset V^{(d)}$, and the same pair $(J,b)$ is a representative of $\text{Max}\ HS_Y$. The previous observation implies that

\[
\text{ord}_Y(\alpha(\xi)) = \text{ord}_X(\xi).
\]

- As we said before, any algorithm of resolution of basic object using this order function will inherit the property of equivariance.
• The functions or invariant functions described in this paper are defined in an analogous way of Hironaka’s inductive functions, so they inherit all the good properties described before.

2.8. The order function, and lower dimensional H-functions.

An example of function on the class of pairs is Hironaka’s $\tau$-function. For each pair $(J, b)$, over $V^{(d)}$, a lower semi-continuous function

$$\tau_{(J,b)} : \text{Sing}(J, b) \to \mathbb{Z}_{\geq 0}$$

is defined (or say, $(-1) \cdot \tau_{(J,b)}$ is upper semi-continuous). The value at $x \in \text{Sing}(J, b)$, say $\tau_{(J,b)}(x)$, is an integer that encodes fundamental information.

When $x$ is a closed point in $V^{(d)}$, $\text{gr}_M(\mathcal{O}_{V^{(d)},x})$ is a polynomial ring over a perfect field, and $\tau_{(J,b)}(x)$ is defined as the least number of variables required to express the homogeneous ideal spanned by $(J + M^{b+1})/M^{b+1}$.

In practical terms, and for the sake of resolution, the invariant $\tau_{(J,b)}(x)$ indicates the number of variables that can be eliminated. This claim will be clarified below, but let us indicate some properties that support it.

In the case of characteristic zero, given $x \in \text{Sing}(J, b)$, and setting $e = \tau_{(J,b)}(x)$, then there is a smooth subscheme of dimension $d - e$, say $V^{(d-e)} \subset V^{(d)}$, together with a pair $(\mathcal{J}, b')$, with the property that a resolution of $(\mathcal{J}, b')$ defines a resolution of $(J, b)$.

This construction can be done in a neighborhood of $x$. The advantage of this reformulation is that $\mathcal{J}$ is an ideal in $V^{(d-e)}$, hence involving $e$ variables less. The underlying idea is, of course, that the smaller the dimension of $V^{(d-e)}$ is, the easier it is to construct a resolution. Here $V^{(d-e)}$ is defined so that, locally, $\text{Sing}(J, b) \subset V^{(d-e)}$, and moreover, $\text{Sing}(J, b) = \text{Sing}(\mathcal{J}, b')$.

Example 2.9. In the case of $f = y^2 + z^3 + x^7 \in k[x, y, z]$, the $\tau$ invariant of the pair $((f), 2)$ is in this case equal to 1 at the origin, and $y$ is the variable which can be eliminated. Here $V^{(d-e)} = V^{(2)} = \text{Spec}(k[x, z])$, and $(\mathcal{J}, b') = ((z^3 + x^7), 2)$.

We now introduce one of the main objects of interest in this work, the so called $r$-dimensional $H$-functions

$$H\text{-ord}^{(r)}_{(J,b)} : \text{Sing}(J, b) \to \mathbb{Q}.$$ These functions are somehow subordinated to the previous $\tau$-function. In fact, if $e = \tau_{(J,b)}(x)$, then at least $e$ variables can be eliminated. In this case we shall define functions $H\text{-ord}^{(r)}_{(J,b)}$ at a suitable neighborhood of $x$, but only for $d - e \leq r \leq d$.

For the case $r = d$, the function $H\text{-ord}^{(d)}_{(J,b)}$ is always defined. In this case, $H\text{-ord}^{(d)}_{(J,b)} = \text{ord}^{(d)}_{(J,b)}$, where

$$\text{ord}^{(d)}_{(J,b)} : \text{Sing}(J, b) \to \mathbb{Q} \quad \text{with} \quad \text{ord}^{(d)}_{(J,b)}(y) = \frac{\nu_y(J)}{b},$$

for $y \in \text{Sing}(J, b)$, and $\nu_y(J)$ denotes the order of $J$ in $\mathcal{O}_{V^{(d)},y}$. Thus, the $d$-dimensional function coincides with Hironaka’s well known order function, namely $\text{ord}_{(J,b)}$. One checks easily that $\text{ord}_{(J,b)}$ is upper semi-continuous.

A property of these functions $H\text{-ord}^{(r)}_{(J,b)}$ is that they are constantly equal to 1 at points of $\text{Sing}(J, b)$, in a neighborhood of $x$, except for

$$H\text{-ord}^{(d-e)}_{(J,b)} : \text{Sing}(J, b) \to \mathbb{Q}.$$ When the characteristic is zero, $H\text{-ord}^{(d-e)}_{(J,b)}$ admits the following description: Set $V^{(d-e)} \subset V^{(d)}$ and $(\mathcal{J}, b')$, as above. Recall that $\text{Sing}(J, b) = \text{Sing}(\mathcal{J}, b')$, finally set

$$H\text{-ord}^{(d-e)}_{(J,b)}(y) = \frac{\nu_y(\mathcal{J})}{b'},$$
for \( y \in \text{Sing}(J, b) \), where \( \nu_y(J) \) denotes the order of \( J \) at \( \mathcal{O}_{V(d-c), y} \). This local description, which holds only in characteristic zero, indicates that (2.9.1) is upper semi-continuous.

The previous definition makes use of the existence of hypersurfaces of maximal contact, which is a particular feature of characteristic zero. In the case of positive characteristic, \( \text{H-ord}^{(d-c)}_{J,b}(y) \) does not admit a local description as in (2.9.2). Moreover, it will be shown that the function (2.9.1) is no longer upper semi-continuous (see Example 2.20).

2.10. Objective of this work.

We shall indicate later how \( \text{H-ord}^{(d-c)}_{J,b}(y) \) is defined over fields of positive characteristic. The behavior of this function is rather untraceable. It has been studied in previous works (e.g. [10], [11], [12], [13], [25]), but only as a refinement of hypersurface singularities. Our results here are directed towards singularities of arbitrary schemes over perfect fields, and the outcome is a refinement of the Hilbert-Samuel stratification.

Set \( r = d - c \). As was previously indicated, in general the functions \( \text{H-ord}^{(r)}_{J,b} : \text{Sing}(J, b) \rightarrow \mathbb{Q} \) are not upper semi-continuous, one cannot expect a nice inductive formulation, as that in (2.9.2), which is valid only in characteristic zero. In this paper we show that this lack of semicontinuity can be somehow bounded: to this end we present two functions on pairs; the roof function, say

\[
(2.10.1) 
R^{(r)}_{J,b} : \text{Sing}(J, b) \rightarrow \mathbb{Q} 
\]

and the floor function, say

\[
(2.10.2) 
F^{(r)}_{J,b} : \text{Sing}(J, b) \rightarrow \mathbb{Q}.
\]

Both \( R^{(r)}_{J,b} \) and \( F^{(r)}_{J,b} \) are upper semi-continuous functions, and

\[
F^{(r)}_{J,b} \leq \text{H-ord}^{(r)}_{J,b} \leq R^{(r)}_{J,b},
\]

In characteristic zero we get an equality at the right hand side. In particular, \( \text{ord}^{(r)}_{J,b} \) is upper semi-continuous.

The objective of this paper is to explore these functions in positive characteristic, and to show that resolution of pairs \((J, b)\) is attained when one the the inequalities is an equality.

The roof functions \( R^{(r)} \) will be discussed in 2.21 and the floor functions \( F^{(r)} \) in 2.25. Some indications on the behavior of the H-functions \( \text{H-ord}^{(r)}_{J,b} \) will be discussed in 2.29.

A precise formulation of the previous statement is given in Theorem 2.27. A first step in this direction requires a harmless reformulation, in which pairs are replaced by Rees algebras (see 2.11). The advantage of this reformulation is that each algebra can be naturally enlarged to a new algebra which is enriched by the action of differential operators. These are called differential Rees algebras, which have been recently studied, due to the strong properties they have, by several authors as Hironaka, Kawanoue-Matsuki, Włodarczyk (e.g. [34], [35], [40], [41], [45], [46], [50], [9], [6], [49]). Moreover, for the purpose of our study we can always restrict attention to these algebras compatible with differential operators.

2.11. From Pairs to Rees algebras.

A pair over \( V^{(d)} \) can be viewed as an algebra. A Rees algebra over \( V^{(d)} \) is an algebra of the form \( \mathcal{G} = \bigoplus_{n \in \mathbb{N}} I_n W^n \), where \( I_0 = \mathcal{O}_{V^{(d)}} \) and each \( I_n \) is a coherent sheaf of ideals. Here \( W \) denotes a dummy variable introduced to keep track of the degree, so \( \mathcal{G} \subset \mathcal{O}_{V^{(d)}[W]} \) is an inclusion of graded algebras. It is always assumed that, locally at any point of \( V^{(d)} \), \( \mathcal{G} \) is a finitely generated \( \mathcal{O}_{V^{(d)}} \)-algebra. Namely, that restricting to an affine set there are local generators, say \( \{ f_{n_1}, \ldots, f_{n_s} \} \), so that

\[
\mathcal{G} = \mathcal{O}_{V^{(d)}}[f_{n_1}W^{n_1}, \ldots, f_{n_s}W^{n_s}] \subset \mathcal{O}_{V^{(d)}[W]}.
\]
We now define the *singular locus* of $\mathcal{G} = \bigoplus I_n W^n$ to be the closed set:

$$\text{Sing}(\mathcal{G}) := \{ x \in V^{(d)} | \nu_r(I_n) \geq n \text{ for each } n \in \mathbb{N} \}.$$  

Fix a monoidal transformation $V^{(d)} \xleftarrow{\pi_C} V_1^{(d)}$ with center $C \subset \text{Sing}(\mathcal{G})$. For all $n \in \mathbb{N}$ there is a factorization of the form

$$I_n \mathcal{O}_{V_1^{(d)}} = I(H_1)^n \cdot I_n^{(1)},$$

where $H_1 = \pi_C^{-1}(C)$ denotes the exceptional hypersurface. This defines a Rees algebra over $V_1^{(d)}$, say $\mathcal{G}_1 = \bigoplus_{n \in \mathbb{N}} I_n^{(1)} W^n$, called the *transform* of $\mathcal{G}$. This transformation will be denoted by

$$(2.11.1) \quad \mathcal{G} \xrightarrow{\pi_C} \mathcal{G}_1 \quad V^{(d)} \xrightarrow{\pi_C} V_1^{(d)} \xrightarrow{\pi_C} \mathcal{G}_1$$

A sequence of transformations will be denoted by:

$$(2.11.2) \quad \mathcal{G} \xrightarrow{\pi_C} \mathcal{G}_1 \xrightarrow{\pi_C} \mathcal{G}_r \quad V^{(d)} \xrightarrow{\pi_C} V_1^{(d)} \xrightarrow{\pi_C} \cdots \xrightarrow{\pi_{C_{r-1}}} V_r^{(d)} \xrightarrow{\pi_{C_r}} \mathcal{G}_r$$

and herein we always assume that the exceptional locus of the composite morphism $V^{(d)} \leftarrow V_r^{(d)}$, say $\{H_1, \ldots, H_r\}$, is a union of hypersurfaces with only normal crossings in $V_r^{(d)}$. A sequence $\text{Sing}(\mathcal{G}_r)$ is said to be a *resolution* of $\mathcal{G}$ if in addition $\text{Sing}(\mathcal{G}_r) = \emptyset$.

A pair $(J, b)$ over $V^{(d)}$ defines an algebra, say

$$\mathcal{G}_{(J,b)} = \mathcal{O}_{V^{(d)}}[JW^b].$$

Note here that $\text{Sing}(J,b) = \text{Sing}(\mathcal{G}_{(J,b)})$, and considering $\mathcal{G} = \mathcal{G}_{(J,b)}$ in (2.11.1), then $\mathcal{G}_1 = \mathcal{G}_{(J_1,b)}$, where $(J_1,b)$ denotes the transform of $(J,b)$. So algebras appear as a naive reformulation of pairs, and a resolution of $\mathcal{G}_{(J,b)}$ is the same as a resolution of $(J,b)$. Furthermore, all the previous discussion, developed in terms of pairs, has a natural analog for Rees algebras. We first discuss, briefly, the formulation of the $\tau$-invariant for algebras over $V^{(d)}$.

**2.12. Hironaka’s $\tau$-invariant.** Fix a Rees algebra $\mathcal{G}$ over $V^{(d)}$ and a closed point $x \in \text{Sing}(\mathcal{G})$. Recall that the *tangent space at* $x$ is $T_{V^{(d)},x} = \text{Spec}(gr_M(\mathcal{O}_{V^{(d)},x}))$. An homogeneous ideal is attached to $\mathcal{G}$ at the closed point $x$, say $I_n(\mathcal{G})$, it is included in $gr_{M,x}(\mathcal{O}_{V^{(d)},x})$, and it is defined as homogeneous ideal generated by the class of $I_n$ at the quotient $\mathcal{M}_M/\mathcal{M}_M^{n+1}$, for all $n$. The *tangent cone* at $x$, say $\mathcal{C}_G(x) \subset T_{V^{(d)},x}$, will be the cone defined by this homogeneous ideal. There is a largest subspace, denoted by $\mathcal{L}_G$, which is included and acting by translations on $\mathcal{C}_G$.

This linear space is called the *space of vertices* of $\mathcal{C}_G(x)$. Finally, the $\tau$-invariant at a closed point is defined by setting $\tau_G(x) = \tau_{G,x}$ to be the codimension of $\mathcal{L}_G,x$ in $T_{V^{(d)},x}$. Here we are going to consider the $\tau$-invariant only at closed points $x$. In this setting, whenever $x$ is closed, $\tau_G(x)$ is the least number of variables required to express generators of the ideal $I_n(\mathcal{G})$ in the polynomial ring $gr_M(\mathcal{O}_{V^{(d)},x})$.

For the particular case of $\mathcal{G} = \mathcal{G}_{(J,b)}$, we get $\tau_G(x) = \tau_{(J,b)}(x)$ at any $x \in \text{Sing}(J,b) = \text{Sing}(\mathcal{G})$.

**2.13. Rees algebras and differential structure.** There are various advantages in formulating invariants in terms of Rees algebras as opposed to their formulation in terms of pairs. One of them arises when studying Rees algebras with a natural compatibility with differential operators.

A Rees algebra $\mathcal{G} = \bigoplus_{n \geq 0} I_n W^n$ over $V^{(d)}$ is said to be a *differential Rees algebra* if locally, say over any open affine set, $D_r(I_n) \subset I_{n-r}$, for any index $n$ and for any differential operator $D_r$ of order $r < n$.

If this property holds for all $k$-linear differential operators, then we say that $\mathcal{G}$ is an *absolute differential Rees algebra* over the smooth scheme $V^{(d)}$. It is convenient to extend the previous definition to the relative context, for example when a smooth morphism $V^{(d)} \xrightarrow{\beta} V^{(d')}$ is fixed.
If the previous property holds for differential operators which are $\mathcal{O}_{V(d')}$-linear, or say, $\beta$-relative operators, then $G$ is said to be a $\beta$-relative differential Rees algebra, or simply $\beta$-differential.

**Proposition 2.14.** ([45] Theorems 3.2 and 4.1) Every Rees algebra $G$ over $V(d)$ admits an extension to a new Rees algebra, say $G \subset Diff(G)$, so that $Diff(G)$ is a differential Rees algebra. It has the following properties:

1. $Diff(G)$ is the smallest differential Rees algebra containing $G$.
2. $Sing(G) = Sing(Diff(G))$.
3. The equality in (2) is preserved by transformations. In particular, any resolution of $G$ defines a resolution of $Diff(G)$, and the converse holds.

The property in (3) says that, for the sake of defining a resolution of $G$, we may always assume that it is a differential Rees algebra. This is an important reduction because, as we shall see, differential Rees algebras have very powerful properties. Further details can be found in [45].

### 2.15. Transversal projections and elimination

Once we fix a closed point $x \in V(d)$ it is very simple to construct, for any positive integer $d' \leq d$, a smooth scheme $V(d')$ together with a smooth morphism $\beta : V(d) \to V(d')$ (a projection), at least when restricting $V(d)$ to an étale neighborhood of $x$. The claim follows, essentially, from the definition of smoothness. In fact, $(V(d), x)$ is an étale neighborhood of $(\mathbb{A}^d, \mathbb{O})$; and plenty of smooth morphisms (plenty of surjective linear transformations) $(\mathbb{A}^d, \mathbb{O}) \to (\mathbb{A}^{d'}, \mathbb{O})$ can be constructed. Note that if $\{x_1, \ldots, x_d\}$ is a regular system of parameters at $\mathcal{O}_{V(d), x}$, then $(V(d), x)$ is an étale neighborhood of $\mathbb{A}^d_k = \text{Spec}(k[x_1, \ldots, x_d])$ at the origin.

Furthermore, given a subspace $S$ of dimension $d - d'$ in $T_{V(d), x}$, one can easily construct $V(d')$ and a smooth $\beta : V(d) \to V(d')$ so that $\ker(d(\beta)) = S$ (here $d(\beta)_x : T_{V(d), x} \to T_{V(d'), \beta(x)}$ is a surjective linear transformation).

Fix now a differential Rees algebra over $V(d)$ and a closed point $x \in Sing(G)$. Recall here that $\tau_G(x) = e$ is the codimension of $L_{G,x} \subset C_{G,x}$ in the tangent space. Set $d'$ so that $d \geq d' \geq d - e$.

For $d'$ in these conditions we say that a smooth morphism $\beta : V(d) \to V(d')$ is transversal to $G$ at $x$ if

$$\ker(d\beta)_x \cap L_{G,x} = \mathbb{O}.$$ 

This condition is open (it holds at points in a neighborhood of $x$), and a smooth morphism $\beta : V(d) \to V(d')$ is said to be transversal to $G$, if this condition holds at any point of $Sing(G)$.

Since $G$ is a differential Rees algebra, it is, in particular, a $\beta$-differential Rees algebra.

**Proposition 2.16.** Assume that $\beta : V(d) \to V(d')$ is transversal to $G$, and that $G$ is $\beta$-differential. Then a Rees algebra $R_{G,\beta}$ is defined over $V(d')$, say

$$\begin{array}{ccc}
G & \xrightarrow{\beta} & R_{G,\beta} \\
V(d) & \xrightarrow{\beta} & V(d')
\end{array}$$

(i.e., $R_{G,\beta} \subset \mathcal{O}_{V(d')}[W]$) with the following properties:

1. The natural lifting of $R_{G,\beta}$, say $\beta^*(R_{G,\beta})$, is a subalgebra of $G$. ([45] Theorem 4.13)
2. $\beta(Sing(G)) \subset Sing(R_{G,\beta})$, and moreover, $\beta|_{Sing(G)} : Sing(G) \to Sing(R_{G,\beta})$ defines a set theoretical bijection of $Sing(G)$ with its image. ([45] 1.15 and Theorem 4.11), or [9] 7.1).
3. Given a smooth sub-scheme $Y \subset Sing(G)$, then $\beta(Y)(\subset Sing(R_{G,\beta}))$ is isomorphic to $Y$. In particular $Y$ defines a transformation of $G$ and also of $R_{G,\beta}$. ([9] Theorem 9.1 (i)).
sequence of monoidal transformations, say $a \beta$ where:

- elimination algebra
- the

Remark 2.18.

The previous Proposition says that given $\beta : V^{(d)} \to V^{(d')}$ transversal to $\mathcal{G}$, and if $\mathcal{G}$ is a $\beta$-differential Rees algebra (e.g., if $\mathcal{G}$ is an absolute differential Rees algebra), then an arbitrary sequence of monoidal transformations, say

$\begin{array}{c}
\beta_i \\
\beta_{i+1} \\
\beta_{i+2} \\
\ldots
\end{array}$

where:

1. For any index $i$, there is an inclusion $(\mathcal{R}_{G,\beta})_i \subset \mathcal{G}_i$.
2. Every $\beta_i$ is transversal to $\mathcal{G}_i$ and $\mathcal{G}_i$ is $\beta_i$-differential.
3. $V_i^{(d')} \xrightarrow{\beta_i(Y_i)} V_i^{(d')}$ denotes the transformation with center $\beta_i(Y_i)$ which is isomorphic to $Y_i$.
4. $(\mathcal{R}_{G,\beta})_i = \mathcal{R}_{\mathcal{G}_i,\beta_i}$ where the latter denotes the elimination algebra of $\mathcal{G}_i$ with respect to $\beta_i$.
5. $\beta_i(Sing(\mathcal{G}_i)) \subset Sing((\mathcal{R}_{G,\beta})_i)$, and $\beta_i(Sing(\mathcal{G}_i)) : Sing(\mathcal{G}_i) \to \beta_i(Sing(\mathcal{G}_i))$ is an identification. In the characteristic zero case, the previous inclusions are equalities, but in positive characteristic, in general, only the inclusion holds.

Remark 2.18. It is convenient to consider the Rees algebra $\mathcal{G}$ to be differential in the formulation of [2.14]. We know that this can be done since they lead to the same resolution (see Proposition 2.14). In fact, in this case, locally at any closed point $x \in Sing(\mathcal{G})$, one can construct a smooth scheme $V^{(d')}$ and a smooth morphism $\beta : V^{(d)} \to V^{(d')}$, and then $\mathcal{G}$ will always be a $\beta$-differential
Rees algebra. In fact an absolute differential Rees algebra is always relative differential for any smooth morphism \( \beta : V^{(d)} \rightarrow V^{(d')}. \)

Fix a Rees algebra \( G = \bigoplus I_n W^n \) over a \( d \)-dimensional smooth scheme \( V^{(d)} \). Lower dimensional H-functions

\[
\text{H-ord}^{(r)}(G) : \text{Sing}(G) \rightarrow \mathbb{Q}_{\geq 0}
\]

will be defined for \( r \) in a certain range \( d' \leq r \leq d \) (for some \( d' \leq d \)). For \( r = d \), the function \( \text{H-ord}^{(d)} \) is usually denoted simply by \( \text{ord} \), we will use this notation along this work. In this case,

\[
(2.19.1) \quad \text{ord}(G)(x) = \min \left\{ \frac{\nu_x(I_n)}{n} \mid n \in \mathbb{N} \right\}
\]

with \( x \in \text{Sing}(G) \).

Facts:

- If \( \tau_G(x) \geq 1 \), then the function is constantly equal to 1 in an open neighborhood of \( x \).
- If \( \tau_G(x) \geq e \), then, in a neighborhood of \( x \), the functions are defined in a range \( d - e \leq r \leq d \). Moreover, \( \text{H-ord}^{(r)}(G) \) is equal to 1 in a neighborhood of \( x \) for \( r \geq d - e + 1 \).
- A particular feature is that, in general, the function \( \text{ord}(G) \) is upper semi-continuous.
- In contrast, if \( \tau_G(x) \geq e > 0 \), the function \( \text{H-ord}^{(d-e)}(G) \) might not be upper semi-continuous. The following example illustrates this fact.

Example 2.20. Fix \( f = z^p + xy^p \in k[x, y, z] \) with \( k \) a perfect field of characteristic \( p > 0 \). In this example, the H-function will be exactly \( \frac{p+1}{p} \) in any closed point of the form \( (x, y, z) = (\lambda, 0, 0) \). Nevertheless, the value of the H-function at the generic point of the line \( y = z = 0 \) will be 1.

Fix a differential Rees algebra \( G \). Let \( e \) be a positive integer and assume that \( \tau_G(x) \geq e \) at any closed point \( x \in \text{Sing}(G) \), so that the function \( \text{Ord}^{(d-e)}(G) : \text{Sing}(G) \rightarrow \mathbb{Q}_{\geq 0} \) will be defined. We also make use of the property (1) in Proposition 2.16 to define, for a given sequence of transformations \( (2.17.1) \), new functions:

\[
\text{Ord}^{(d-e)}(G_i) : \text{Sing}(G_i) \rightarrow \mathbb{Q}_{\geq 0}.
\]

To this end fix \( \beta : V^{(d)} \rightarrow V^{(d')} \) transversal to \( G \) for \( d' = d - e \). This induces a sequence \( (2.17.2) \). Set, for each index \( i \leq r \):

\[
\text{Ord}^{(d-e)}(G_i)(x) = \text{ord}((R_{G, \beta})_i)(\beta_i(x)).
\]

In \( 2.23 \) we indicate some general properties of the function \( \text{ord}((R_{G, \beta})_i) \).

Claim 2.22. The function \( \text{H-ord}^{(d-e)}(G_i)(x) \) will be defined so that for any \( x \in \text{Sing}(G) \):

\[
\text{H-ord}^{(d-e)}(G_i)(x) \leq \text{Ord}^{(d-e)}(G_i)(x).
\]

That is, the upper semi-continuous function \( \text{Ord}^{(d-e)} \) will provide an upper bound for our H-function.

2.23. The functions \( \text{Ord}^{(d-e)}(G_i) \) have been studied in [9]. The main results are:

1. The functions are intrinsic to the sequence of transformations \( (2.17.1) \). Namely, they are independent of the choice of the transversal morphism \( \beta : V^{(d)} \rightarrow V^{(d')} \) in \( (2.17.2) \). ([9 Theorem 10.1])

2. If the characteristic is zero, both functions \( \text{H-ord}^{(d-e)}(G) \) and \( \text{Ord}^{(d-e)}(G) \) coincide. In particular, in such case the function \( \text{H-ord}^{(d-e)}(G) \) is upper semi-continuous.
(3) It is proved in [9] Part 5 and 10.4 that, up to an induction hypothesis on \( d - e \), a sequence \((2.17.2)\) can be constructed so that either the singular locus of the transform is empty, the \( \tau \)-invariant increases, or the elimination algebra \((R_{G, \beta})\) is *monomial*, i.e., it is defined by an invertible sheaf of ideals supported on the exceptional locus, say
\[
(2.23.1) \quad (R_{G, \beta})_r = \mathcal{O}_{V_r^{(d-e)}} [I(H_1)^{\alpha_1} \ldots I(H_r)^{\alpha_r} W^s],
\]
where \( H_i \) is the strict transform of the exceptional component introduced by \( \pi_{\beta_{r-1}}(Y_{r-1}) \).

**Remark 2.24.** In characteristic zero, it is easy to extend a sequence which is monomial, in the sense of \((2.23.1)\), to a resolution of singularities. This extension can be constructed by choosing centers in a simple combinatorial manner. However this is not the case in positive characteristic, which is quite more involve (see Theorem 2.27).

**2.25. On the lower-bound function and tamed H-functions.**

A remarkable property of the H-functions, which was studied in [6, 7.4], is that they enable us to assign, to a sequence of transformations of \( G \), a monomial algebra which turns out to be a useful tool in the study of singularities. The monomial algebra assigned to \((2.17.2)\) is
\[
(2.25.1) \quad \mathcal{M}_r W^s = \mathcal{O}_{V_r^{(d-e)}} [I(H_1)^{h_1} \ldots I(H_r)^{h_r} W^s],
\]
where each exponent \( h_i \) is defined by setting, for \( i = 0, \ldots, r-1 \):
\[
\frac{h_{i+1}}{s} = H\text{-ord}^{(d-e)}(G_i)(\xi_i) - 1,
\]
where \( \xi_i \) denotes the generic point of \( Y_i \).

**Claim 2.26.** The following inequalities hold for any sequence as that on \((2.17.1)\):
\[
\text{ord}(\mathcal{M}_r W^s)(x) \leq H\text{-ord}^{(d-e)}(G_r)(x) \leq \text{Ord}^{(d-e)}(G_r)(x)
\]
and for all \( x \in \text{Sing}(G_r) \).

This indicates that at least our untraceable H-function fits between two upper semi-continuous functions. The next Theorem gives conditions under which the H-function has a nice and tame behavior. Moreover, when this conditions holds, this leads to a resolution of the algebra.

**Theorem 2.27.** Fix a differential Rees algebra \( G \). Fix a positive integer \( e \) and assume, as in \((2.21)\), that \( \tau_0(x) \geq e \) at any closed point \( x \in \text{Sing}(G) \). Consider a sequence of transformations \((2.17.2)\) with the property in \((2.23.1)\), namely that the elimination algebra is monomial. Set \( \mathcal{M}_r W^s \) as in \((2.25.1)\). If for any \( x \in \text{Sing}(G_r) \)
\[
(2.27.1) \quad H\text{-ord}^{(d-e)}(G_r)(x) = \text{ord}(\mathcal{M}_r W^s)(x),
\]
then the combinatorial resolution of \( \mathcal{M}_r W^s \) can be lifted to a sequence of monoidal transformations over \( G_r \), say
\[
(2.27.2) \quad G \xrightarrow{V(d)} G_1 \xrightarrow{\pi_{Y_1}} \cdots \xrightarrow{\pi_{Y_{r-1}}(d)} G_r \xrightarrow{V_r(d)} \cdots \xrightarrow{\pi_{Y_{N-1}}(d)} G_N
\]
which is either a resolution of \( G \) (i.e., \( \text{Sing}(G) = \emptyset \)), or \( \tau_{G_N}(x) \geq e + 1 \) at any closed point \( x \in \text{Sing}(G_N) \) (improvement of the \( \tau \)-invariant).

This Theorem extends [6, Theorem 8.13], where the case \( e = 1 \) is treated. The theorem and its proof will be address here in Theorem 7.3 (see also Remark 7.3).

**Definition 2.28.** \( G_r \) is said to be in the *strong monomial case* (or say \( H\text{-ord}^{(d-e)}(G_r) \) is *tamed*) when the setting of Theorem 2.27 holds, namely when the equality in \((2.27.1)\) holds at any \( x \in \text{Sing}(G_r) \).
2.29. On the definition of the functions $H$-ord$^{(d-e)}$.

We have indicated, so far, that these H-functions will be bounded between two upper semi-continuous functions. The results in this paper aim to the explicit computation of the function in positive characteristic. This will be achieved through the notion of *presentations*, which we discuss below.

To clarify our strategy, let us first indicate what is known in the case $e = 1$ ($d - e = d - 1$). Given a diagram as (2.17.2), locally at any point $x \in \text{Sing}(G_r)$, a presentation is defined as

$$(2.29.1) \quad \mathcal{P} = \mathcal{P}(\beta_r, z, f_n(z)),$$

where

- $\{z = 0\}$ is a $\beta_r$-section (i.e., $\{z = 0\}$ is a section of $\beta_r : V_r^{(d)} \rightarrow V_r^{(d')}$).
- $f_n(z) = z^n + a_1 z^{n-1} + \cdots + a_n \in \mathcal{O}_{V(d-1)}[z]$ and $f_n(z)W^n \in G_r$.

Moreover, a presentation can be defined at $x$ so that:

$$(2.29.2) \quad \text{H-ord}^{(d-1)}(G_r)(x) = \min_{1 \leq j \leq n} \left\{ \frac{\nu_{\beta_r}(x)(a_j)}{j}, \text{ord}((G_{\beta_r})(\beta_r(x))) \right\}.$$

In fact, the presentations of the form (2.29.1) were the tool which lead us to the proof of Theorem 5.11 for the case $e = 1$ (see [6, Theorem A.7]). We shall indicate in 6.2 how the previous result will lead to the following statement:

Suppose that $d' = d - e$ now for $e > 1$. Locally at any $x \in \text{Sing}(G_r)$, there is a presentation, say

$$(2.29.3) \quad \mathcal{P} = \mathcal{P}(\beta_r, z_1, \ldots, z_e, g_{n_1}(z_1), \ldots, g_{n_e}(z_e))$$

where:

- $\{z_1 = \cdots = z_e = 0\}$ is a $\beta_r$-section,
- $g_{n_i}(z_i)W^{n_i} \in G_r$, and for each index, they have of the form:
  $$\begin{align*}
g_{n_1}(z_1) &= z_1^{n_1} + a_1^{(1)} z_1^{n_1-1} + \cdots + a_{n_1}^{(1)} \in \mathcal{O}_{V(d-1)}[z_1], \\
g_{n_2}(z_2) &= z_2^{n_2} + a_1^{(2)} z_2^{n_2-2} + \cdots + a_{n_2}^{(2)} \in \mathcal{O}_{V(d-2)}[z_2], \\
&\vdots \\
g_{n_e}(z_e) &= z_e^{n_e} + a_1^{(e)} z_e^{n_e-1} + \cdots + a_{n_e}^{(e)} \in \mathcal{O}_{V(d-e)}[z_e],
\end{align*}$$

However, this kind of presentation is not well suited to obtain an expression as that in (2.29.2), the reason is that the coefficients are not all in dimension $d - e$.

In this paper we overcome this difficulty by proving the existence of the so called *simplified presentations*, say

$$(2.29.4) \quad s\mathcal{P} = s\mathcal{P}(\beta_r, z_1, \ldots, z_e, f_{n_1}(z_1), \ldots, f_{n_e}(z_e)),$$

which fulfill the additional condition:

$$\begin{align*}
f_{n_1}(z_1) &= z_1^{n_1} + a_1^{(1)} z_1^{n_1-1} + \cdots + a_{n_1}^{(1)} \in \mathcal{O}_{V(d-1)}[z_1], \\
f_{n_2}(z_2) &= z_2^{n_2} + a_1^{(2)} z_2^{n_2-2} + \cdots + a_{n_2}^{(2)} \in \mathcal{O}_{V(d-2)}[z_2], \\
&\vdots \\
f_{n_e}(z_e) &= z_e^{n_e} + a_1^{(e)} z_e^{n_e-1} + \cdots + a_{n_e}^{(e)} \in \mathcal{O}_{V(d-e)}[z_e].
\end{align*}$$

This simplified presentations are, to some extend, a generalization of Weierstrass Preparation Theorem. Note that, as oppose to (2.29.3), all coefficients are now in dimension $d - e$, i.e., $a_j^{(i)} \in \mathcal{O}_{V(d-e)}$. This latter property will enable us to extend the previous assertion. Namely that the value of the H-function at $x$ is:

$$(2.29.5) \quad \text{H-ord}^{(d-e)}(G_r)(x) = \min_{1 \leq j \leq n_i, 1 \leq i \leq e} \left\{ \frac{\nu_{\beta_r}(x)(a_j^{(i)})}{j_i}, \text{ord}((G_{\beta_r})(\beta_r(x))) \right\}.$$
The construction of this kind of presentations appears in Theorem 6.8. Simplified presentations will allow us to view each equation in (2.29.4) as a polynomial in one different variable. Using this latter fact, the arguments known for \( \ell' = \ell - 1 \), namely (2.29.2), will be extended to arbitrary \( \ell' \), say (2.29.5).

In particular, these simplified presentations will be used to extend the main results in [6, Main Theorem 1 and Theorem 8.13], and give numerical conditions in terms of the H-functions, under which the sequence (2.17.2) can be easily extended to a resolution.

The main tool used throughout this paper are the differential Rees algebras and their properties. The hope is that a better understanding of these algebras will lead to the conditions in Theorem 2.27, and hence to resolution of singularities. Here we mean resolution in the sense of Hironaka, namely by successive blow-ups along centers included in the closed Hilbert-Samuel stratum (i.e., not in the simplified form introduced in [20]).

In [7] it is proven the resolution of surfaces embedded in a 3-dimensional ambient space. The technics developed in this paper will enable us to extend this result to prove the embedded resolution of 2-dimensional scheme embedded in arbitrary dimension (see Theorem 7.8). This last result has also been obtained by others authors in [1], [13] (arithmetic case!), [17].

3. Weak equivalence

3.1. The word invariant was already used in the previous discussion. Hironaka provides this notion with a very precise meaning, which is also related with his notion of equivalence. This notion is discussed below.

In fact, here an invariant of a singular point will be a value assigned to it, and subject to very precise conditions expressed in terms of this equivalence. It will be proved that the value of the H-function at a singular point, discussed in this paper, fulfills these conditions.

Briefly speaking, the equivalence imposes conditions which are related with the form of compatibility with monoidal transformations and smooth morphisms.

3.2. Fix on the smooth scheme \( V^{(d)} \) a set of smooth hypersurfaces with normal crossings, say \( E = \{ H_1, \ldots, H_r \} \). Let \( G = \bigoplus I_n W^n \) be a Rees algebra over \( V^{(d)} \), and let

\[
V^{(d)} \xleftarrow{\pi} U
\]

be a smooth morphism.

There is a natural notion of pull-backs of the Rees algebra \( G \) and the set \( E \), say to a Rees algebra \( G_U \) and a set \( E_U \). Here \( E_U \) is the collection obtained as the pull-backs of the hypersurfaces in \( E \). The Rees algebra \( G_U \) is defined by setting \( G_U = \bigoplus (I_n)_U W^n \) to be the natural lifting of \( G \) to \( U \). This notion of pull-back will be denoted by

\[
V^{(d)} \xleftarrow{\pi} U,
G, E \quad G_U, E_U
\]

Observe here that the singular locus of the Rees algebra \( G \) is compatible with pull-backs, i.e.,

\[
\text{Sing}(G_U) = \pi^{-1}(\text{Sing}(G)).
\]

**Definition 3.3.** Given \( G \) and \( E \) as above, a local sequence of \( G \) and \( E \) is a sequence

\[
V^{(d)} \xleftarrow{\pi_1} V_1^{(d)} \xleftarrow{\pi_2} \cdots \xleftarrow{\pi_r} V_r^{(d)}
\]

\[
G, E \quad G_1, E_1 \quad G_r, E_r
\]

where each \( V_i^{(d)} \) is either a pull-back or a monoidal transformation along a center \( C_i \subset \text{Sing}(G_i) \) which has normal crossing with the union of the exceptional hypersurfaces in \( E_i \),
for \( i = 0, \ldots, r - 1 \). In this latter case we set \( E_{i+1} \) to be the union of the strict transforms of hypersurfaces in \( E_i \), together with the the exceptional locus of the monoidal transformation.

**Definition 3.4.** Fix two Rees algebras \( \mathcal{G} \) and \( \mathcal{G}' \) and a set of exceptional hypersurfaces \( E \) in the smooth scheme \( V^{(d)} \). We say that \( \mathcal{G} \) and \( \mathcal{G}' \) are weakly equivalent if:

(i) \( \text{Sing}(\mathcal{G}) = \text{Sing}(\mathcal{G}') \).

(ii) A local sequence of \( \mathcal{G} \), say:

\[
V^{(d)} \xrightarrow{\pi_1} \tilde{V}^{(d)}_1 \xrightarrow{\pi_2} \cdots \xrightarrow{\pi_r} \tilde{V}^{(d)}_r
\]

defines a local sequence of \( \mathcal{G}' \) (and vice versa), and \( \text{Sing}(\mathcal{G}_i) = \text{Sing}(\mathcal{G}'_i) \) for \( i = 0, \ldots, r \).

**Remark 3.5.** The notion of the weak equivalence is preserved by a local sequence, namely if \( \mathcal{G} \) and \( \mathcal{G}' \) are weakly equivalent as before, then also their transforms \( \mathcal{G}_r \) and \( \mathcal{G}'_r \) are weakly equivalent.

A first example of equivalence arises when we consider the integral closure of a Rees algebra \( \mathcal{G} \).

In fact, if \( \tilde{\mathcal{G}} \) denotes the integral closure of \( \mathcal{G} \), then \( \tilde{\mathcal{G}} \) is again a Rees algebra. The following theorem includes a relation of weak equivalence between \( \mathcal{G} \) and \( \tilde{\mathcal{G}} \).

**Theorem 3.6.**

1. Fix two Rees algebras \( \mathcal{G} \) and \( \tilde{\mathcal{G}} \) with the same integral closure. Then, \( \mathcal{G} \) and \( \tilde{\mathcal{G}} \) are weakly equivalent.

2. Fix a Rees algebra \( \mathcal{G} \). Let \( \text{Diff}(\mathcal{G}) \) be the differential Rees algebra attached to \( \mathcal{G} \) (see 2.13). Then \( \mathcal{G} \) and \( \text{Diff}(\mathcal{G}) \) are weakly equivalent.

**Proof.** (1) See [21, Proposition 5.4].

(2) This property is also known as Giraud’s Lemma, see [21, Theorem 4.1].

### 3.7. We address here the notion of invariant, as needed in our development. Given \( \mathcal{G} \) over \( V^{(d)} \), an invariant attached to \( x \in \text{Sing}(\mathcal{G}) \) is a value, say \( \gamma(x, \mathcal{G}) \), which is subject to the condition:

\[
(*) \quad \gamma(x, \mathcal{G}) = \gamma(x, \mathcal{G}')
\]

whenever \( \mathcal{G} \) and \( \mathcal{G}' \) are weakly equivalent when restricted to some neighborhood of \( x \).

A first example of invariant is that of the value \( \tau_\mathcal{G}(x) \) in 2.12 (see also [12] and [4]). It will be proved here in Theorem 6.12 (1) that the value \( \text{H-ord}^{(r)}(\mathcal{G})(x) \) is an invariant, for any point \( x \in \text{Sing}(\mathcal{G}) \).

### 4. The slope of a hypersurface and the weak equivalence

In this section, we will restrict attention to the description of the \( d - 1 \)-dimensional H-function at a point in the highest multiplicity locus of a hypersurface. In such context, this value, introduced by Hironaka, is a rational number which is defined as an optimal slope. We present here the slope as a refinement of the multiplicity at the point (see Definition 4.2). This will be done firstly in terms of a transversal projection, and then it will be shown to be independent of the choice of such projection (Theorem 4.11).

#### 4.1. Slope of a monic polynomial.** Fix a hypersurface \( X \) embedded in a smooth scheme \( V^{(d)} \) and a closed \( n \)-fold point \( x \) of \( X \) (i.e., a point of multiplicity \( n \)). After suitable restriction, in étale topology, a smooth morphism \( V^{(d)} \xrightarrow{\beta} V^{(d-1)} \) can be defined so that \( X \) is expressed by a monic polynomial of degree \( n \), of the form

\[
f_n(z) = z^n + a_1z^{n-1} + \cdots + a_n \in \mathcal{O}_{V^{(d-1)}}[z];
\]
where \( z \) is a global section of \( \mathcal{O}_{V(d)} \) and \( z = 0 \) is a \( \beta \)-section. We abuse notation and say that \( z \) is a transversal section of \( \beta \). This says that, after suitable restriction in étale topology, both at \( x \) and \( \beta(x) \), the restricted map \( \beta|_X \):

\[
\begin{array}{ccc}
X & \xrightarrow{\beta} & V^{(d)} \\
\downarrow \beta|_X & & \downarrow \beta \\
V^{(d-1)} & \leftarrow & W
\end{array}
\]

is finite. So locally at any \( y \in V^{(d-1)} \) we may view \( X \) as defined by the monic polynomial in (4.1.1). In particular, the fiber over \( y \), say \( \beta^{-1}(y) \), is given by \( \tilde{f}_n(z) = z^n + a_1 z^{n-1} + \cdots + a_n \in k(y)[z] \), where \( k(y) \) is the residue field at the point.

To simplify notation, let \( f_n W^n \) denote the Rees algebra \( \mathcal{O}_{V(d)}[f_n(z)W^n] \). Note that \( \text{Sing}(f_n W^n) \) is the set of \( n \)-fold points of the hypersurface. Here we will assume that \( \text{Sing}(f_n W^n) \) has no components of codimension one in \( V^{(d)} \), and this will ensure that \( f_n(z) \neq z^n \) for any expression as (4.1.1).

**Definition 4.2.** Assume, as before, that \( X \) is defined by the monic polynomial in (4.1.1). The slope of \( f_n(z)W^n \) at \( y \in V^{(d-1)} \) is the rational number

\[
SL(f_n(z)W^n)(y) = \min_{1 \leq j \leq n} \left\{ \frac{\nu_y(a_j)}{j} \right\}.
\]

Geometrically, the slope defined by the equation (4.1.1) is the biggest rational number \( q \) so that all pairs \( (\nu_y(a_j), n - j) \) lie above the line through \((0, n)\) and \((nq, 0)\):

![Diagram](https://via.placeholder.com/150)

Changes on the variable \( z \) imply changes on (4.1.1), and hence on the value (4.2.1). We aim to find the biggest possible value of the slope at the fixed point \( y \). A first step in this direction will be address in Remark (4.1.1).

The following technical lemma and remark gather some results to be used in this and further sections, which will be needed to establish the optimality of the rational number.

**Lemma 4.3.** (Zariski’s Multiplicity Lemma, [50], Chapter VIII §10, Corollary 1 to Theorem 24). Let \( f_n \) be as in (4.1.1), defining \( X \) as in (4.1.2).

1. Fix \( y \in \beta(\text{Sing}(f_n W^n)) \). Then \( \tilde{f}_n(z) = (z - \pi)^n \in k(y)[z] \), for a suitable \( \pi \in k(y) \), the residue field at \( \mathcal{O}_{V^{(d-1)}}(y) \). In particular, the fiber \( \beta^{-1}(y) \) has a unique point which is rational.
2. Assume that \( C \subset \text{Sing}(f_n W^n) \) is smooth and irreducible. \( \beta(C) \) is smooth and moreover \( \beta|_C \) induces an isomorphism \( \beta|_C : C \xrightarrow{\cong} \beta(C) \) (see Proposition (2.10) (3)). In particular, if \( V^{(d-1)} \) is affine, there is a global section \( \alpha \in \mathcal{O}_{V^{(d-1)}} \) so that \( (z - \alpha) \in I(C) \subset \mathcal{O}_{V^{(d)}} \).
(3) Suppose that \( C' \) is a smooth and irreducible component of \( \beta(\text{Sing}(f_nW^n)) \). There is a unique irreducible component \( C \subset \text{Sing}(f_nW^n) \) such that \( \beta(C) = C' \). Moreover, \( C \) and \( C' \) are isomorphic and hence \( C \) is smooth.

Further details can be found in [46, 47] and [9]. In fact, (1), (2), and (3) are a byproduct of Zariski Multiplicity Lemma. Note that (1) says that \( \beta|_{\text{Sing}(f_nW^n)} : \text{Sing}(f_nW^n) \to \beta(\text{Sing}(f_nW^n)) \) is a set theoretical bijection, and that corresponding points have the same residue field. (2) and the first part of (3) follow essentially from this fact. As for the second half of (3), note that \( \beta|_C : C \to \beta(C) = C' \) is a finite birational morphism, and that \( C' \) is normal.

**Remark 4.4.** (1) Fix \( y \in V^{(d-1)} \). Let \( \tilde{f}_n(z) = z^n + a_1 z^{n-1} + \cdots + a_n \in k(y)[z] \) be the class of \( f_n(z) \) on the fiber. Then, \( Sl(f_n(z)W^n)(y) = 0 \) if and only if \( \tilde{f}_n(z) \neq z^n \).

When \( y \in \beta(\text{Sing}(f_nW^n)) \), then \( \tilde{f}_n(z) = (z - \alpha)^n \). A suitable change of variables of the form \( z_1 = z + \gamma \), with \( \gamma \in \mathcal{O}_{V^{(d-1)},y'} \), can be defined with the property that \( \bar{\gamma} = \bar{\alpha} \) in \( k(y) \). In particular, the restriction to the fiber over \( y \) is \( \tilde{f}_n(z_1) = z_1^n \), and hence \( Sl(f_n(z_1))(y) > 0 \). Moreover, we claim that in this case \( Sl(f_n(z_1))(y) \geq 1 \). To check this, notice that the condition \( Sl(f_n(z_1))(y) > 0 \) implies that there is a unique point of \( X = V(f_n(z_1)) \), say \( y' \in V^{(d)} \), dominating \( y \). If \( \{x_1, \ldots, x_{\ell}\} \) is a regular system of parameters at \( \mathcal{O}_{V^{(d)},y'} \), then \( \{x_1, x_1, \ldots, x_{\ell}\} \) is a regular system of parameters at \( \mathcal{O}_{V^{(d)},y'} \). As \( f_n(z_1) \) has multiplicity \( n \) at \( \mathcal{O}_{V^{(d)},y'} \), it follows that \( f_n(z) = z^n + b_1 z^{n-1} + \cdots + b_n \in \langle x_1, x_1, \ldots, x_{\ell} \rangle \), and hence each \( b_i \in \langle x_1, x_1, \ldots, x_{\ell} \rangle \).

(2) Fix \( x \in C \subset \text{Sing}(f_nW^n) \) and set \( x = \beta(x) \). One can argue as in Lemma 4.3 (2), to show that after a suitable change of the form \( z_1 = z - \alpha \), with \( \alpha \in \mathcal{O}_{V^{(d-1)},x} \), one obtains \( Sl(f_n(z)W^n)(y) > 0 \). Here \( y \) denotes the generic point of \( \beta(C) \). In particular, \( Sl(f_n(z_1)W^n)(y) \geq 1 \).

(3) The previous discussion applies also when we fix \( x \in C' \subset \beta(\text{Sing}(f_nW^n)) \), with \( C' \) smooth and irreducible. In fact, a suitable change of variables of the form \( z_1 = z + \alpha \) with \( \alpha \in \mathcal{O}_{C',x} \) (locally at \( x \)) can be considered so that \( Sl(f_n(z_1)W^n)(y) > 0 \), where \( y \) denotes the generic point of \( C' \). Moreover, part (1) implies that \( Sl(f_n(z_1)W^n)(y) \geq 1 \).

We will now provide a criterium that will ensure conditions under which the rational number \( Sl(f_n(z)W^n)(y) \) is optimal.

**Definition 4.5.** Fix a hypersurface \( X \subset V^{(d)} \), a smooth morphism \( V^{(d)} \to V^{(d-1)} \), and a transversal parameter \( z \) so that \( f_n(z) = z^n + a_1 z^{n-1} + \cdots + a_n \in \mathcal{O}_{V^{(d-1)},z} \) defines the hypersurface \( X \) after a suitable restriction. Fix \( y \in V^{(d-1)} \), and set \( q = Sl(f_n(z)W^n)(y) \in \mathbb{Q} \). Let \( r_j = \nu_q(a_j) \) \((j = 1, \ldots, n)\) denote the order of each coefficient at \( \mathcal{O}_{V^{(d-1)},y} \). Fix a regular system of coordinates at \( \mathcal{O}_{V^{(d-1)},y} \), say \( \{x_1, \ldots, x_{\ell-1}\} \). At the completion, say \( \tilde{\mathcal{O}}_{V^{(d-1)},y} = k(y)[[x_1, \ldots, x_{\ell-1}]] \), define \( f_n(z) = z^n + \partial_1 z^{n-1} + \cdots + \partial_n \), with

\[
\tilde{\alpha}_j = \sum_{i \geq r_j} A_{ij} \in k(y)[[x_1, \ldots, x_{\ell-1}]],
\]

where \( A_{ij} \) is a homogeneous polynomial of degree \( i \) in the variables \( x_1, \ldots, x_{\ell-1} \). Here \( \ell = d - 1 \) if \( y \) is a closed point in \( V^{(d)} \).

The weighted initial form of \( f_n(z) \) (over \( y \)) is defined as

\[
\text{w-in}_y(f_n(z)) = \sum_{0 \leq j \leq n} A_{ij}^q z^{n-j} \in gr(\mathcal{O}_{V^{(d-1)},y})[Z],
\]

where each \( A_{ij}^q \) is weighted homogeneous of degree \( jq \), and where \( A_{ij}^q = 0 \) if \( jq \notin \mathbb{Z} \).

Note that \( \text{w-in}_y(f_n(z)) \) is defined in \( gr(\mathcal{O}_{V^{(d-1)},y})[Z] \), and that it is weighted homogeneous of degree \( nq \) if \( Z \) is given weight \( q \) and each \( X_i = In(x_i) \) has weight 1 for \( i = 1, \ldots, d - 1 \). To ease notation we provide \( z \) with weight \( q \) and each \( x_i \) with weight 1 at the ring of formal power series.
Remark 4.6. Suppose that $SL(f_n(z)W^n)(y) = 0$. Then, $w^{-\infty}_y(f_n(z))$ is weighted homogeneous of degree 0, if $z$ is endowed with weight $q = 0$ and each $x_i$ is given weight 1. In such case, $w^{-\infty}_y(f_n(z))$ is defined in $k(y)[Z]$ and there is a natural identification of this polynomial with the equation that defines the fiber of the hypersurface over the point $y$, namely $w^{-\infty}_y(f_n(z)) = f_n(Z) = k(y)[Z]$, where $f_n(z)$ is the equation that defines the fiber.

Remark 4.7. Note that in (1.5.4) we have that $A^n_0 = 1$, and hence $w^{-\infty}_y(f_n(z))$ is a monic polynomial of degree $n$. Moreover, we claim that $w^{-\infty}_y(f_n(z)) \neq Z^n$.

In fact, one can check that $w^{-\infty}_y(f_n(z))$ is an $n$-th power if and only if $w^{-\infty}_y(f_n(z)) = (Z + A)^n$ for some $A \in gr(O_{V^{(d-1)}y})$. In this case, $A$ must be homogeneous of degree $q$. If this occurs, then $q \in Z$, and hence there is an element $\alpha \in O_{V^{(d-1)}y}$ so that $In_y(\alpha) = A$. The change of variables $z_1 = z + \alpha$ gives rise to a strictly higher slope, i.e., $SL(f_n(z_1)W^n)(y) > SL(f_n(z)W^n)(y)$.

The previous discussion shows that a change of the form $z_1 = z + \alpha$ can increase the slope if and only if $w^{-\infty}_y(f_n(z))$ is an $n$-th power.

As $Sing(f_nW^n)$ has no components of codimension 1 in $V^{(d)}$, by assumption, one can check that after finitely many changes of the variable $z$ as above, we may assume that $w^{-\infty}_y(f_n(z))$ is not an $n$-th power. This leads to the following definition.

Definition 4.8. A monic polynomial $f_n(z)$ is said to be in normal form at a point $y \in V^{(d-1)}$ if the weighted initial form $w^{-\infty}_y(f_n(z)W^n)$ is not an $n$-th power at $gr(O_{V^{(d-1)}y})[Z]$.

Proposition 4.9. Fix a point $y \in V^{(d-1)}$ and a polynomial $f_n(z) = z^n + a_1z^{n-1} + \cdots + a_n \in O_{V^{(d-1)}y}[z]$ which is in normal form at $y$, i.e., assume that $z$ is such that $w^{-\infty}_y(f_n(z))$ is not an $n$-th power at $gr(O_{V^{(d-1)}y})[Z]$. Then $y \in \beta(Sing(f_nW^n))$ if and only if $q = SL(f_n(z)W^n)(y) \geq 1$.

Proof. If $y \in \beta(Sing(f_nW^n))$, and since $w^{-\infty}_y(f_n(z))$ is not an $n$-th power, then $SL(f_n(z)W^n)(y) > 0$. Under these conditions Remark 4.4 (1) says that $SL(f_n(z)W^n)(y) \geq 1$.

Conversely, suppose that $SL(f_n(z)W^n)(y) \geq 1$. Lemma 4.3 (1) says that $SL(f_n(z)W^n)(y) > 0$ implies that there is a unique point, say $y' \in X = V(f_n(z))$, dominating $y$. Fix a regular system of parameters $\{x_1, \ldots, x_{d-1}\}$ at $O_{V^{(d-1)}y}$, and recall that $\{z, x_1, \ldots, x_{d-1}\}$ is a regular system of parameters at $O_{V^{(d-1)}y}$. Finally, the condition $SL(f_n(z)W^n)(y) \geq 1$ implies that $\nu_y(a_i) \geq i$, and hence that $y'$ is an $n$-fold point of $X$.

Remark 4.10. Let the assumptions be as in (1.1.2), where $f_n(z) = z^n + a_1z^{n-1} + \cdots + a_n \in O_{V^{(d-1)}y}[z]$. A function, say $q_\beta : Sing(f_nW^n) \rightarrow \mathbb{Q}_{>0}$, will be defined by setting:

$$q_\beta(x) := \max_{z_1} \{SL(f_n(z_1)W^n)(\beta(x))\},$$

where $z_1 = z + \alpha$ for all the possible choices of $\alpha \in O_{V^{(d-1)}y}(x)$ (see Remark 4.4 (1)). Note that, if $f_n(z)$ is in normal form at $\beta(x)$, then Remark 4.7 ensures that $q_\beta(x) = SL(f_n(z)W^n)(\beta(x))$.

Theorem 4.11. Fix a projection $V^{(d)} \rightarrow V^{(d-1)}$ together with a monic polynomial $f_n(z) = z^n + a_1z^{n-1} + \cdots + a_n \in O_{V^{(d-1)}y}[z]$, where $\{z = 0\}$ is a section of $\beta$. Consider a point $x \in Sing(f_nW^n)$ and assume that $f_n(z)$ is in normal form at $\beta(x)$. Let $q$ denote the slope of $f_n(z)$ at $\beta(x)$. The rational number $q$ is completely characterized by the weak equivalence class of the algebra $G = O_{V^{(d)}y}f_nW^n$ in a neighborhood of $x$.

Corollary 4.12. Fix a hypersurface $X \subset V^{(d)}$ of maximum multiplicity $n$, and two projections $\beta : V^{(d)} \rightarrow V^{(d-1)}$ and $\beta' : V^{(d)} \rightarrow V^{(d-1)}$, each is the setting of (4.1.2). For any $n$-fold point $x \in X$:

$$q_\beta(x) = q_{\beta'}(x).$$
Proof. The rational number \( q_\beta(x) \) is completely determined in terms of the weak equivalence class of \( G = \mathcal{O}_{V(d)}[f_nW^n] \) at \( x \), and therefore it is independent of the chosen projection. \( \Box \)

Proof of Theorem 4.11 The proof of this Theorem is based on the so called Hironaka’s trick (see [19, 7.1]).

Set \( x = \beta(x) \). As \( x \in \text{Sing}(f_nW^n) \), Lemma 4.3 (1) says that \( \overline{f}_{\eta}(z) = (z - \overline{\alpha})^n \) (with \( \alpha \in k(x) \)). Here \( \overline{f}_{\eta}(z) \) denotes the restriction to the fiber over \( x \). Since \( f_n(z) \) is a normal form at \( x \), Remark 4.4 (1) ensures that \( \overline{\alpha} = 0 \) and hence \( z \) vanishes at \( x \). A regular system of parameters \( \{ x_1, \ldots, x_t \} \) at \( \mathcal{O}_{V(d-1),x} \) can be extended to a regular system of parameters \( \{ z, x_1, \ldots, x_t \} \) at \( \mathcal{O}_{V(d),x} \). Note also that \( x \in \text{Sing}(f_nW^n) \), so \( \nu_{\alpha}(a_j) \geq j \) for \( j = 1, \ldots, n \).

Express the monic polynomial as \( f_n(z) = z^n + \tilde{a}_1z^{n-1} + \cdots + \tilde{a}_n \) at the completion \( \hat{\mathcal{O}}_{V(d),x} \), and set
\[
\tilde{a}_j = A_j^q + \tilde{A}_j \in k(x)[[x_1, \ldots, x_t]]
\]
where \( A_j^q \) is homogeneous of degree \( jq \) and \( \tilde{A}_j \) has order \( > jq \). Here \( A_j^q = 0 \) if \( jq \not\in \mathbb{Z} \). Recall that \( f_n(z) \) is in normal form, i.e., that
\[
(4.12) \ w\text{-in}_x(f_n(z)) = Z^n + \sum_{j=1}^n A_j^q Z^{n-j} \in \text{gr}_x(\mathcal{O}_{V(d-1)})[Z]
\]
is not an \( n \)-th power. Denote by \( r_j = \nu_{\alpha}(a_j) \) (\( j = 1, \ldots, n \)) the order of each coefficient at \( \mathcal{O}_{V(d-1),x} \). Note that \( A_j^q = 0 \) if \( \frac{r_j}{q} > 1 \).

Stage A: Let \( V(d) \times \mathbb{A}^1 \) denote the product of \( V(d) \) with the affine line. The projection on the first coordinate enables us to take the pull-back of \( f_n(z) \), in a neighborhood of \((x, 0) \in V(d) \times \mathbb{A}^1 \).

The natural extension
\[
(4.12) \ V(d) \times \mathbb{A}^1 \xrightarrow{\beta \times \text{id}} V(d-1) \times \mathbb{A}^1
\]
is a smooth morphism that maps \((x, 0)\) to \((x, 0)\). The natural identification of \( w\text{-in}_{(x, 0)}(f_n(z)) \) with \( w\text{-in}_x(f_n(z)) \) guarantees that \( w\text{-in}_{(x, 0)}(f_n(z)) \) is not an \( n \)-th power. This identification together with Remark 4.4 (1) ensure that
\[
\text{SL}(f_n(z)W^n)((x, 0)) = \text{SL}(f_n(z)W^n)(x) = q \geq 1.
\]

Fix coordinates \( \{ z, x_1, \ldots, x_e, t \} \) locally at \((x, 0)\), here \( \{ z, x_1, \ldots, x_e \} \) is the regular system of parameters at \( \mathcal{O}_{V(d),x} \) mentioned before. Consider the monoidal transformation with center \( p_0 = (x, 0) \) and let \( p_1 \) be the intersection of the new exceptional hypersurface, say \( H_1 \), with the strict transform of \( x \times \mathbb{A}^1 \).

The point \( p_1 \) can be identified with the origin of the \( U_t \)-chart, \( (U_t = \text{Spec}(k[\hat{z}_1, \ldots, \hat{z}_e, t])) \). Now set
\[
\tilde{f}^{(1)}_n(z_1) = z_1^n + t^{r_1-1}\tilde{a}_1^{(1)} z_1^{n-1} + \cdots + t^{r_n-n}\tilde{a}_n^{(1)},
\]
at the completion of the local ring of at \( p_1 \), and check that:
\[
t^{r_j-j}a_j^{(1)} z_1^{n-j} = t^{r_j-j}(A_j^q + \tilde{A}_j) z_1^{n-j}
\]
with \( \gamma_j > 0 \) for \( j = 1, \ldots, n \). Here \( z_1 = \hat{z}_1 \) and \( a_j^{(1)} \) is the strict transform of \( a_j \).

This process can be iterated \( N \)-times, defining a sequence of monoidal transformations at \( p_1, \ldots, p_{N-1} \), where each \( p_j \) is the point of intersection of the new exceptional component, say \( H_j \), with the strict transform of \( x \times \mathbb{A}^1 \).

The final strict transform of \( f_n(z) \) at the \( U_t \)-chart is given by
\[
(4.12) \ f^{(N)}_n(z_N) = z_N^n + t^{N(r_1-1)}\tilde{a}_1^{(N)} z_N^{n-1} + \cdots + t^{N(r_n-n)}\tilde{a}_n^{(N)}.
\]
where
\[ t^{N(r_j-j)}a_j^{(N)}z_N^{-j} = t^{N(r_j-j)}(A_j^q + t^{\gamma_j})z_N^{-j} \]
with \( \gamma_j > 0 \) for \( j = 1, \ldots, n \).

It may occur after this process of monoidal transformations that \( \{ f_{n}^{(N)} = 0 \} \cap H_{N} \) is a 2-codimensional component of the \( n \)-fold points of \( \{ f_{n}^{(N)} = 0 \} \). In that case, we will fix \( N \) sufficiently large, and we look for the largest number of successive monoidal transformations that can be defined with center in codimension 2. We explain below how these centers will be chosen for this new sequence of transformations.

The proof will also show that the rational number \( q \) can be characterized in terms of these monoidal transformations:

- **Stage B:** Firstly, consider the monoidal transformation along the center \( (z_N, t) \), if such center is permissible. Denote \( \tilde{\beta} \) by \( z_{N+1} \) at the \( U_{i} \)-chart. The transform is
\[ f_{n}^{(N+1)}(z_{N+1}) = z_{N+1} + t^{N(r_1-1)}a_1^{(N+1)}z_{N+1}^{-1} + \cdots + t^{N(r_n-n)}a_n^{(N+1)}, \]
where
\[ t^{N(r_j-j)}a_j^{(N+1)}z_{N+1}^{-j} = t^{N(r_j-j)}(A_j^q + t^{\gamma_j})z_{N+1}^{-j} \]
with \( \gamma_j > 0 \) for \( j = 1, \ldots, n \).

After applying \( \ell \) monoidal transformations along centers of codimension 2 of the form \( (z_{N+i}, t) \), the exponents of \( t \) in each coefficient is \( N(r_j-j) - \ell j \). Therefore \( (z_{N+i}, t) \) is a permissible center whenever \( N(r_j-j) - \ell j \geq j \) for all \( j \in \{1, \ldots, n\} \). In particular, this condition requires that
\[ \ell \leq \min_{1 \leq j \leq n} \left\{ N(r_j-j) - 1 \right\} = N(q-1) - 1. \]

The geometric interpretation of the previous sequence of \( \ell \)-monoidal transformation can be described as follows: Set \( X_N = \{ f_{n}^{(N)} = 0 \} \) (see (4.12.3)) and let \( H_N \) denote the exceptional hypersurface \( t = 0 \). The sequence we have previously constructed can be expressed in terms of the diagram
\[
\begin{array}{ccc}
X_N & \xrightarrow{V_{N}^{(d+1)}} & X_{N+1} \\
V_{N+1}^{(d+1)} & \xrightarrow{\pi_{N+1}} & V_{N+1}^{(d+1)} \\
V_{N+1}^{(d+1)} & \xrightarrow{\pi_{N+2}} & \cdots \xrightarrow{\pi_{N+\ell}} & V_{N+\ell}^{(d+1)}
\end{array}
\]
where if \( H_{N+i+1} \) denotes the exceptional hypersurface of \( \pi_{N+i} \), then the centers of this monoidal transformations are defined by \( X_{N+i+1} \cap H_{N+i+1} \).

Let \( \tilde{\beta} \) denote the morphism \( V^{(d) \times A^1} \to V^{(d-1) \times A^1} \) in (4.12.3). This morphism has a natural lifting to the sequence of monoidal transformations of length \( N \) in stage A, and also to the sequence (4.12.4). This is guaranteed by Proposition 2.10 (3). In particular, for each index \( i = 0, \ldots, \ell \), the previous sequence defines morphisms
\[ \tilde{\beta}_{N+i} : V_{N+i}^{(d+1)} \to V_{N+i}^{(d)}. \]

Set
\[ \ell_N = [N(q-1) - 1]. \]

We finally claim that for \( \ell = \ell_N \), we have that \( X_{N+\ell} \cap H_{N+\ell} \) is not a permissible center for \( X_{N+\ell} \) (see (4.12.4)).

In fact, whenever \( Nq \notin \mathbb{Z} \), and after applying \( \ell_N \) monoidal transformations along these centers of codimension 2, one gets \( V((z_{N+i}, t)) \subseteq X_{N+i} \), and \( 0 < \text{Sl}(f_{n}^{(N+i, N)}w^n)(\xi_H) < 1 \). So \( H_{N+i} = \{ t = 0 \} \) cannot be a component of \( \tilde{\beta}_{N+i}(\text{Sing}(f_{n}^{(N+i, N)}w^n)) \) (see Proposition 4.9).
On the other hand, if $Nq \in \mathbb{Z}$, then $N(q-1) - 1$ is a positive integer. In this case, after applying $N(q-1) - 1$ monoidal transformations along these 2-codimensional centers, the final strict transform of $f_n^{(N)}(z)$ is given by

$$f_n^{(N+\ell_N)}(z) = z_{N+\ell_N}^n + t^{N(r_1-q)}N_{1}^{(N+\ell_N)}z_{N+\ell_N}^{n-1} + \cdots + t^{N(r_n-q_n)}N_{n}^{(N+\ell_N)},$$

at the chart of interest. We claim that $X_{N+\ell_N} \cap H_{N+\ell_N}$ is not a permissible center.

Note that $SL(f_n^{(N+\ell_N)}(z_{N+\ell_N})W^n)(\xi_H) = 0$. Remark 4.4 shows that $w^{-\infty}(f_n^{(N+\ell_N)}(z_{N+\ell_N}))$ can be identified with the equation defining the fiber over $\xi_H$:

$$f_n^{(N+\ell_N)}(z_{N+\ell_N})|_{t=0} = z_{N+\ell_N}^n + \sum_{j=1}^{n} A_j q^{-j} z_{N+\ell_N}^{n-j}.$$

The expression of the right hand side can be naturally identified with $w^{-\infty}(f_n(z))$ (see (4.12.1)). As we assume that $w^{-\infty}(f_n(z))$ is not an $n$-th power, Proposition 4.9 together with Remark 4.4 ensure that $H_{N+\ell_N}$ is not a component of $\tilde{\beta}_{N+\ell_N}(\text{Sing}(f_n^{(N+\ell_N)}W^n))$.

In Remark 4.13 we will apply the following discussion to show that $q$ is totally characterized by Hironaka’s weak equivalence class of the $n$-fold points of the hypersurface $\{f_n = 0\}$. Notice that the construction of the sequences in Stage A) and Stage B), together with (4.12.6), lead to the equality

$$(4.12.7) \quad \lim_{N \to \infty} \frac{\ell_N}{N} = q - 1.$$

**Remark 4.13.** We claim that the rational number $q$ can be expressed in terms of Hironaka’s weak equivalence class. Recall here that the weak equivalence class of $f_n W^n$ is defined in the context of $k$-algebras of finite type, whereas the local rings $\mathcal{O}_{\mathcal{V}(\beta, x)}$ are not within this class.

The claim is straightforward when the point $x$ is closed. As this function is not upper semicontinuous, it requires some clarification if $x \in \text{Sing}(f_n W^n)$ is not a closed point. Let $Y$ denote the variety with generic point $x$. Since the weak equivalence class allows restriction to open sets, we may assume that $Y$ is smooth.

Fix a closed point $p$ at $Y$ and fix local coordinates $\{z, x_2, \ldots, x_d\}$ at $\mathcal{O}_{\mathcal{V}(\beta, x)}$, so that $\{x_2, \ldots, x_d\}$ is a regular system of parameters at $\mathcal{O}_{\mathcal{V}(\beta, x)}$. We may assume, applying Lemma 4.3 (2), that

(1) $I(Y) = (z, x_2, \ldots, x_d)$,

(2) $f = z^n + a_1 z^{n-1} + \cdots + a_n$,

(3) $I(\beta(y)) = (x_2, \ldots, x_d)$.

In particular, $gr I(\beta(y))(\mathcal{O}_{\mathcal{V}(\beta, x), \beta(p)}) = \mathcal{O}_{\beta}(\mathcal{V}(\beta, x), \beta(p))[X_2, \ldots, X_d]$. Set $x = \beta(x)$ and let $k(x)$ be the quotient field of $\mathcal{O}_{\beta(y), \beta(p)}$. Note that $w^{-\infty}(f_n) \in gr I(\beta(y))(\mathcal{O}_{\mathcal{V}(\beta, x), \beta(p)})$ can be naturally identified with $w^{-\infty}(f_n)$ via the inclusion $gr I(\beta(y))(\mathcal{O}_{\mathcal{V}(\beta, x), \beta(p)}) \subseteq gr k(x)(\mathcal{O}_{\mathcal{V}(\beta, x), \beta(p)})$. In this setting, one can check that the sequences of transformations used in the previous proof to determinate the rational number $q$ are expressed in terms of the weak equivalence class of $f_n W^n$. This proves the claim for the case in which $x$ is a non-closed point of $X$.

5. Slope of a Rees algebra and the $d - 1$-dimensional H-function ($\tau \geq 1$)

5.1. We rephrase the results and invariants discussed in Section 4 but now in the context of Rees algebras. Here Theorem 5.11 parallels Theorem 4.11 in the previous section.

Throughout the section we fix a Rees algebra $\mathcal{G} = \bigoplus I_n W^n$ over $V^{(d)}$ and assume that $\tau_\mathcal{G} \geq 1$ along closed points of Sing($\mathcal{G}$). Consider a transversal projection $V^{(d)} \xrightarrow{\beta} V^{(d-1)}$, and assume in addition that $\mathcal{G}$ is a $\beta$-differential Rees algebra (see 2.13).
Fix a Rees algebra relative to \( P \) or simply by \( \text{(5.5.2)} \) presentation
\[
(O_{V(\ell)}[f_n(z)W^n, \Delta^j(f_n(z))W^n-j]_{1 \leq j \leq n-1} \otimes \beta^*(\mathcal{R}_{\mathcal{G},\beta})),
\]
where \( \Delta^j \) are suitable \( \beta \)-differential operators of order \( j \). Moreover, \( \mathcal{R}_{\mathcal{G},\beta} \) is non-zero whenever \( \text{Sing}(\mathcal{G}) \) is not of codimension one in \( V(\ell) \).

\[\text{Proof.} \ [\text{Proposition 2.11.}]\]

\( \Box \)

**Remark 5.4.** The differential operators \( \Delta^j \) in the previous proposition are the operators obtained by the Taylor morphism: This is a morphism of \( S \)-algebras, say \( \text{Tay} : S[Z] \rightarrow S[Z,T] \), defined by setting \( \text{Tay}(Z) = Z + T \) (Taylor expansion). Here
\[
\text{Tay}(f(Z)) = f(Z + T) = \sum \Delta^r(f(Z))T^r,
\]
and these operators \( \Delta^r : S[Z] \rightarrow S[Z] \) are defined by this morphism. It is well known that \( \{\Delta^0, \Delta^1, \ldots, \Delta^r\} \) is a basis of the free module of \( S \)-differential operators of order \( r \). The same applies here for \( O_{V(\ell-1)}[z] \): the set \( \{\Delta^0, \Delta^1, \ldots, \Delta^n\} \) spans the sheaf of differential operators of order \( r \) relative to the smooth morphism \( \beta : V(\ell) \rightarrow V(\ell-1) \). Moreover, as \( V(\ell) \) is étale over \( V(\ell-1) \times \mathbb{A}^1 \), the previous set also generated \( \text{Diff}f^*_\beta(\beta \text{-linear differential operators of order } r) \).

**Definition 5.5.** (Presentations). Fix, after suitable restriction in étale topology, a projection \( V(\ell) \rightarrow V(\ell-1) \) transversal to a simple \( \beta \)-relative differential Rees algebra \( \mathcal{G} \). Assume that \( \text{Sing}(\mathcal{G}) \) has no components of codimension one and that
\[\text{i)} \quad \text{There is a } \beta \text{-section } z \text{ (or global section so that } \{dz\} \text{ is a basis of the locally free module of } \beta \text{-differentials, say } \Omega^1_{\beta}).\]
\[\text{ii)} \quad \text{There is an element } f_n(z)W^n \in \mathcal{G}, \text{ where } f_n(z) \text{ is a monic polynomial of order } n, \text{ say}\]
\[
f_n(z) = z^n + a_1z^{n-1} + \cdots + a_n \in O_{V(\ell-1)}[z],
\]
where each \( a_i \) is a global function on \( V(\ell-1) \).

In this case Proposition 5.3 holds, namely \( \mathcal{G} \) has the same integral closure as
\[
(O_{V(\ell)}[f_n(z)W^n, \Delta^j(f_n(z))W^n-j]_{1 \leq j \leq n-1} \otimes \beta^*(\mathcal{R}_{\mathcal{G},\beta})).
\]
We say that \( \beta : V(\ell) \rightarrow V(\ell-1) \), the \( \beta \)-section \( z \), and \( f_n(z) = z^n + a_1z^{n-1} + \cdots + a_n \) define a presentation of \( \mathcal{G} \). These data will be denoted by:
\[
\mathcal{P}(\beta : V(\ell) \rightarrow V(\ell-1), z, f_n(z) = z^n + a_1z^{n-1} + \cdots + a_n),
\]
or simply by \( \mathcal{P}(\beta, z, f_n(z)) \).

**Definition 5.6.** Fix a Rees algebra \( \mathcal{G} \) and a presentation \( \mathcal{P}(\beta, z, f_n(z)) \). Define the slope of \( \mathcal{G} \) relative to \( \mathcal{P} \) at a point \( y \in V(\ell-1) \) as
\[
\text{Sl}(\mathcal{P})(y) := \min \left\{ \frac{\nu^\ell(a_j)}{j}, \text{ord}(\mathcal{R}_{\mathcal{G},\beta})(y) \right\} = \min \{\text{Sl}(f_n(z)W^n)(y), \text{ord}(\mathcal{R}_{\mathcal{G},\beta})(y)\}. 
\]
Remark 5.7. A change of variables of the form \( z_1 = z + \alpha, \alpha \in \mathcal{O}_{V^{(d-1)}} \) (a global section of \( V^{(d-1)} \)), gives rise to a new presentation defined in a natural way, say \( \mathcal{P}_1 = \mathcal{P}_1(\beta, z_1, f'_n(z_1)) \).

Assume first that \( Sl(\mathcal{P})(y) = Sl(f_n(z)W^n)(y) < ord(\mathcal{R}_{G,\beta})(y) \). In this case, there is a change of the form \( z_1 = z + \alpha \), so that the new presentation \( \mathcal{P}_1 \) has bigger slope at \( y \) if and only if \( w\text{-in}_y(f_n(z)) \) is an \( n \)-th power (see Remark 5.7).

On the other hand, if \( Sl(\mathcal{P})(y) = ord(\mathcal{R}_{G,\beta})(y) \), the slope at \( y \) cannot increase by any change of the presentation of this type.

Definition 5.8. Fix a Rees algebra \( \mathcal{G} \). A presentation \( \mathcal{P} = \mathcal{P}(\beta, z, f_n(z)) \) is said to be in normal form at \( y \in V^{(d-1)} \) if one of the following two conditions holds:

- Either \( Sl(\mathcal{P})(y) = ord(\mathcal{R}_{G,\beta})(y) \),
- or \( Sl(\mathcal{P})(y) = Sl(f_n(z)W^n)(y) < ord(\mathcal{R}_{G,\beta})(y) \) and \( w\text{-in}_y(f_n(z)) \) is not an \( n \)-th power.

Remark 5.9. Fix, as in Definition 5.3, a Rees algebra \( \mathcal{G} \), a transversal projection \( V^{(d)} \xrightarrow{\beta} V^{(d-1)} \), and assume now that we fix a point \( y \in \beta(\text{Sing}(\mathcal{G})) \). Suppose given two different presentations \( \mathcal{P}_1 = \mathcal{P}_1(\beta, z, f_n(z)) \) and \( \mathcal{P}_2 = \mathcal{P}_2(\beta, z', g_m(z')) \), both in normal form at \( y \). Theorem 5.11 will show that

\[ Sl(\mathcal{P}_1)(y) = Sl(\mathcal{P}_2)(y). \]

Moreover, it will show that this rational number is indeed independent of the chosen projection \( \beta \).

The following result parallels Proposition 4.9.

Proposition 5.10. Let \( \mathcal{G} \) be a Rees algebra and let \( \mathcal{P} = \mathcal{P}(\beta, z, f_n(z)) \) be a presentation. Fix a point \( y \in V^{(d-1)} \) and assume that \( \mathcal{P} \) is in normal form at \( y \). Then, \( y \) is a point of \( \beta(\text{Sing}(\mathcal{G})) \) if and only if \( Sl(\mathcal{P})(y) \geq 1 \).

Proof. Firstly assume that \( Sl(\mathcal{P})(y) \geq 1 \). Denote by \( x \in V^{(d)} \) the unique point of the fiber \( \beta^{-1}(y) \) defined by \( z = 0 \). Fix a regular system of parameters \( \{x_1, \ldots, x_l\} \) at \( \mathcal{O}_{V^{(d-1)},y} \). Since \( Sl_y(\mathcal{P}) \geq 1 \), then \( \nu_y(a_j) \geq j \) (for \( j = 1, \ldots, n \)) and \( ord(\mathcal{R}_{G,\beta})(y) \geq 1 \). Set \( \mathcal{P} = (z, x_1, \ldots, x_l) \), and note that \( f_n(z) \in P^n \). Check now that \( V(\langle z, x_1, \ldots, x_l \rangle) \subset (\text{Sing}(\mathcal{G}) \text{ see also Proposition } 2.16(2)) \).

For the converse, assume that \( y \in \beta(\text{Sing}(\mathcal{G})) \). In this case, \( ord(\mathcal{R}_{G,\beta})(y) \geq 1 \).

Since \( \mathcal{P} \) is in normal form at \( y \), one of the following two cases can occur:

1. \( Sl(\mathcal{P})(y) = ord(\mathcal{R}_{G,\beta})(y) \geq 1 \).
2. \( Sl(\mathcal{P})(y) = Sl(f_n(z)W^n)(y) < ord(\mathcal{R}_{G,\beta})(y) \) and \( w\text{-in}_y(f_n(z)) \) is not an \( n \)-th power. Then Proposition 4.9 ensures that \( Sl(\mathcal{P})(y) \geq 1 \).

\( \Box \)

Theorem 5.11. Fix a Rees algebra \( \mathcal{G} \), and assume that \( \tau_G \geq 1 \) along closed points of \( \text{Sing}(\mathcal{G}) \). Fix a point \( x \in \text{Sing}(\mathcal{G}) \) and consider a presentation \( \mathcal{P} = \mathcal{P}(\beta, z, f_n(z)) \) which is in normal form at \( \beta(x) \). Then, the rational value \( Sl(\mathcal{P})(\beta(x)) \) is completely characterized by the weak equivalence class of \( \mathcal{G} \) in a neighborhood of \( x \).

Proof. Recall that \( Sl(\mathcal{P})(x) = \min\{Sl(f_n(z)W^n)(x), ord(\mathcal{R}_{G,\beta})(x)\} \).

- Firstly assume that \( q := Sl(f_n(z)W^n)(x) < ord(\mathcal{R}_{G,\beta})(x) \). In this case, we will argue as in Theorem 4.11 to prove our claim. In our coming discussion, we make us of the fact that the transformation law of \( \mathcal{R}_{G,\beta} \) is that defines for Rees algebras (see (24.14)).

Fix the same notation as in the proof of Theorem 4.11 and consider \( N \)-monoidal transformations at \( p_0, p_1, \ldots, p_{N-1} \) followed by \( \ell_N \) transformations at codimension 2, where

\[ \ell_N = \begin{cases} 
N(q - 1) - 1 & \text{if } Nq \notin \mathbb{Z}, \\
N(q - 1) - 1 & \text{if } Nq \in \mathbb{Z}.
\end{cases} \]

We claim that the highest possible number of transformations defined by blowing-up centers of codimension 2 (in the sense of Stage B) is exactly this number \( \ell_N \) (which is completely characterized by \( N \) and \( q \)).
The sequence of \( N + \ell \) monoidal transformations

\[
\begin{array}{cccccccc}
G' & G_1 & \cdots & G_N & G_{N+1} & \cdots & G_{N+\ell} \\
V^{(d)} \times \mathbb{A}^1 & V_1^{(d+1)} & \cdots & V_N^{(d+1)} & V_{N+1}^{(d+1)} & \cdots & V_{N+\ell}^{(d+1)}
\end{array}
\]

(see (2.11.2)) gives rise to

\[
\begin{array}{cccccccc}
\mathcal{R}'_{G,\beta} & (\mathcal{R}_G)_{1} & \cdots & (\mathcal{R}_G)_{N} & (\mathcal{R}_G)_{N+1} & \cdots & (\mathcal{R}_G)_{N+\ell}
\end{array}
\]

together with morphisms \( \tilde{\beta_i} : V_i^{(d+1)} \rightarrow V_i^{(d)} \) (see (4.12.3)). In addition, each \( (\mathcal{R}_G,\beta)_i \) is also defined as the elimination algebra of \( G_i \) via \( \beta_i \) (see (3) in (2.17.2)).

Denote by \( H \) the exceptional hypersurface introduced by the last of these transformations. Set \( (\mathcal{R}_G,\beta)' = (\mathcal{R}_G,\beta)_{N+\ell} \).

To finish the proof, assume now that \( \tau_q \not\in \mathbb{Z} \), we have \( 0 \leq \text{Sl}(\mathcal{P}'(\xi_H)) = \text{Sl}(f_n'(z)W^n)(\xi_H) < 1 \), so \( H \) is not a component of \( \beta'(\text{Sing}(G')) \) (see Proposition 5.10 and Remark 4.4 (3)).

On the contrary, if we assume now that \( \tau_q \in \mathbb{Z} \), then \( \text{Sl}(\mathcal{P}'(\xi_H)) = \text{Sl}(f_n'(z)W^n) = 0 \). Remark 4.6 ensures that \( \text{w-in}_{\xi_H}(f_n'(z')) \) is an \( n \)-th power, so Proposition 5.10 and Remark 4.4 (3) applies here to show that \( H \) is not a component of \( \beta'(\text{Sing}(G')) \).

To finish the proof, assume now that \( \text{Sl}(\mathcal{P})(x) = \text{ord}(\mathcal{R}_G,\beta)(x) \). Check that \( \text{Sl}(\mathcal{P}'(\xi_H)) = \text{ord}(\mathcal{R}_G,\beta)'(\xi_H) < 1 \) after the transformations indicated before, and hence \( H \) is not a component of \( \beta'(\text{Sing}(G')) \).

The previous discussion shows that the value \( \text{Sl}(\mathcal{P})(\beta(x)) \) is totally characterized by the weak equivalence class of \( G \) by arguing as it was done in (1.12.7).

**Corollary 5.12.** Let \( G \) be a Rees algebra. Assume that \( \tau_G \geq 1 \) along closed point of \( \text{Sing}(G) \). Fix a point \( x \in \text{Sing}(G) \) and consider two different presentations \( \mathcal{P}_1 = \mathcal{P}(\beta_1, z_1, f_1(z_1)) \) and \( \mathcal{P}_2 = \mathcal{P}(\beta_2, z_2, f_2(z_2)) \) which are in normal form at \( \beta_1(x) \) and \( \beta_2(x) \), respectively. Then,

\[
\text{Sl}(\mathcal{P}_1)(\beta_1(x)) = \text{Sl}(\mathcal{P}_2)(\beta_2(x)).
\]

**Proof.** Follows straightforward from Theorem 5.11.

The previous discussion leads to the following definition:

**Definition 5.13.** Fix a Rees algebra \( G \) and assume that \( \tau \geq 1 \) along \( \text{Sing}(G) \). A function with rational values, called the \( d-1 \)-dimensional \( H \)-function, say

\[
\text{H-ord}^{(d-1)}(G)(-) : \text{Sing}(G) \rightarrow \mathbb{Q}_{\geq 0},
\]

is defined by setting

\[
\text{H-ord}^{(d-1)}(G)(x) := \text{Sl}(\mathcal{P})(\beta(x)) = \min_{1 \leq j \leq n} \left\{ \frac{v_{\beta(x)}(a_j)}{j} \text{ord}(\mathcal{R}_G,\beta)(\beta(x)) \right\},
\]

at any point \( x \in \text{Sing}(G) \), where \( \mathcal{P} = \mathcal{P}(\beta, z, f_n(z)) = z^n + a_1z^{n-1} + \cdots + a_n \) is a presentation in normal form at \( \beta(x) \).
Corollary 5.12 (or Theorem 5.11) ensures that the previous function is well-defined. Namely, it is intrinsic to \( G \), with independence of \( \beta \) and of the presentations. Further corollaries can be stated as follows:

**Corollary 5.14.**

1. Recall that two Rees algebras \( G \) and \( G' \) with the same integral closure are also weakly equivalent. In particular, \( \text{Sing}(G) = \text{Sing}(G') \), and both H-functions coincide, i.e.,

\[
\text{H-ord}^{(d-1)}(G)(x) = \text{H-ord}^{(d-1)}(G')(x)
\]

at any point \( x \in \text{Sing}(G) = \text{Sing}(G') \).

2. Similar statement holds for the Rees algebras \( G \) and \( \text{Diff}(G) \) (see 2.13). In fact, both are weakly equivalent; so at any point \( x \in \text{Sing}(G) = \text{Sing}(\text{Diff}(G)) \):

\[
\text{H-ord}^{(d-1)}(G)(x) = \text{H-ord}^{(d-1)}(\text{Diff}(G))(x).
\]

6. Simplified presentations and the \( d - r \)-dimensional H-functions (\( \tau \geq r \))

**6.1.** Let \( G \) be a differential Rees algebra over \( V^{(d)} \), as defined in 2.13. Fix a closed point \( x \in \text{Sing}(G) \) and assume that \( \tau_{G,x} \geq r \). A notion of presentations was introduced in Definition 5.5 for the case \( r = 1 \), in terms of suitable morphisms \( V^{(d)} \to V^{(d-1)} \). These presentations were, in turn, the tool that enabled us to define the H-functions in the \( d-1 \)-dimensional case, namely \( \text{H-ord}^{(d-1)}(G)(x) \). In this section, we address the general case \( \tau_{G,x} \geq r \). In 6.2 we initiate the discussion of presentations which will lead to the definition of a function in terms of a smooth morphism \( V^{(d)} \beta \to V^{(d-r)} \). In Theorem 6.8 it is proved that such presentations can be chosen in a simplified form, called simplified presentation. The generalized Weierstrass Preparation Theorem to be discussed in this section will be the key tool for this simplification.

The lower dimensional H-functions will be introduced in Definition 6.13. They will appear as the most natural extension of Definition 6.13 to the case \( r > 1 \). The value \( \text{H-ord}^{(d-r)}(G)(x) \) will be defined, firstly, in terms of simplified presentations, and finally Theorem 6.12 (1) will prove that this value is an invariant, and hence it is independent of any choice.

These functions will lead to some applications in singularity theory which will be addressed in Section 7.

**6.2. The case \( \tau \geq 2 \).**

Let \( G \) be a differential Rees algebra. Fix a closed point \( x \in \text{Sing}(G) \). Suppose that \( \tau_{G,x} \geq 2 \) and fix a transversal projection \( V^{(d)} \beta \to V^{(d-2)} \) (see 2.15). We will proceed essentially in two steps. We shall first indicate how to construct a factorization of the form

\[
\begin{array}{ccc}
V^{(d)} & \xrightarrow{\beta} & V^{(d-2)} \\
\beta_1 & & \beta_2 \\
V^{(d-1)} & \xleftarrow{\beta} & V^{(d-2)}
\end{array}
\]

This diagram will allow us to define a coarse presentation in the setting of 6.13. We then proceed in a second step to construct a suitable change of the previous factorization of \( \beta \). This last step will finally enable us to define a simplified presentation in the sense of 2.13.

In this first step, we make use of [4, Theorem 6.4], which ensures that if \( \tau_{G,x} \geq 2 \), then \( \tau_{\mathcal{R}_G,\beta_2 \beta_1(x)} \geq 1 \). This will enable us to apply twice Proposition 5.3. Note here that the existence of \( \beta_1 \) and \( \beta_2 \) together with 5.3 will provide us with a coarse presentation, so that \( G \) will have
the same integral closure as the algebra
\[ O_{V(\delta)}[h_t(z_1)W^\ell, \Delta_{z_1}(h_t(z_1))W^{\ell-j_1}, g_m(z_2)W^m, \Delta_{z_2}(g_m(z_2))W^{m-j_2}]_{1 \leq j_1 \leq \ell - 1, 1 \leq j_2 \leq m - 1 \odot \beta^*(\mathcal{R}_{G, \beta})} \]
(see Notation \[\text{(5.2)}\]), where

- \( h_t(z_1) \in O_{V(\delta-1)}[z_1] \),
- \( g_m(z_2) \in O_{V(\delta-2)}[z_2] \),

are monic polynomials on the transversal sections \( z_1 \) and \( z_2 \), respectively. Let us draw attention to the fact that the coefficients of \( h_t(z_1) \) are in \( O_{V(\delta-1)} \), whereas we aim to define a notion of slope involving polynomials with coefficients in \( O_{V(\delta-2)} \) (simultaneous elimination of two variables).

This is the second step addressed in next proposition. It is proved that, locally in \( \acute{e}tale \) topology, there is a simplified presentation; so that \( G \) and
\[ O_{V(\delta)}[f'_n(z'_1)W^\ell, \Delta_{z'_1}(f'_n(z'_1))W^{\ell-j_1'}, g'_m(z'_2)W^m, \Delta_{z'_2}(g'_m(z'_2))W^{m-j_2'}]_{1 \leq j'_1 \leq \ell - 1, 1 \leq j'_2 \leq m - 1 \odot \beta^*(\mathcal{R}_{G, \beta})} \]
have the same integral closure, where

- \( f'_n(z'_1) \in O_{V(\delta-2)}[z'_1] \),
- \( g'_m(z'_2) \in O_{V(\delta-2)}[z'_2] \),

are monic polynomials on sections \( z'_1 \) and \( z'_2 \), respectively. Note that now both are polynomials with coefficients in \( O_{V(\delta-2)} \). The strategy used to accomplish this second step will be done by changing the factorization of \( \beta \) in \( \text{(6.2.1)} \).

**Proposition 6.3.** Let \( G \) be a differential Rees algebra and let \( x \in \text{Sing}(G) \) be a closed point at which \( \tau_{G,x} \geq 2 \). Then at a suitable neighborhood of \( x \), a transversal morphism, say \( V(\delta) \xrightarrow{\beta} V(\delta-2) \), can be constructed in such a way that:

- there are global sections \( z_1, z_2 \), and \( \{d_1z_1, d_2z_2\} \) is a basis of the module of \( \beta \)-differentials, say \( \Omega^1_G \), and
- there are two elements \( f_nW^n, g_mW^m \in G \) of the form:

** \[ f_n(z_1) = z_1^n + a_1z_1^{n-1} + \cdots + a_n \in O_{V(\delta-2), \beta(x)}[z_1] \]
** \[ g_m(z_2) = z_2^m + b_1z_2^{m-1} + \cdots + b_m \in O_{V(\delta-2), \beta(x)}[z_2] \]

** \[ \text{and } G \text{ has the same integral closure as} \]

\[ O_{V(\delta)}[f_n(z_1)W^n, \Delta_{z_1}(f_n(z_1))W^{n-\alpha}, g_m(z_2)W^m, \Delta_{z_2}(g_m(z_2))W^{m-\gamma}]_{1 \leq \alpha \leq n - 1, 1 \leq \gamma \leq m - 1 \odot \beta^*(\mathcal{R}_{G, \beta})}. \]

Here \( \mathcal{R}_{G, \beta} \) denotes the elimination algebra, and \( \Delta_{z_1} \) are as in Remark \[\text{(5.4)}\]. In addition, \( \mathcal{R}_{G, \beta} \) is non-zero whenever \( \text{Sing}(G) \) is not of co-dimension two locally at \( x \).

**Definition 6.4.** (Simplified Presentations for \( \tau \geq 2 \)). Let the setting be as above. We say that
\[ sP(\beta, z_1, z_2, f_n(z_1), g_m(z_2)) \]
defines a simplified presentation of \( G \).

**Idea of the proof of Proposition 6.3.** Fix \( x \in \text{Sing}(G) \), so that \( \tau_{G,x} \geq 2 \). We will first indicate how to produce a diagram as \[\text{(6.2.1)}\]. Once this task is achieved, we will construct a scheme \( V(\delta-1) \), and two smooth morphisms \( V(\delta) \xrightarrow{\delta_1} V(\delta-1) \) and \( V(\delta-1) \xrightarrow{\delta_2} V(\delta-2) \), so that the following diagram commutes:

\[ \begin{array}{ccc}
V(\delta-1) & \xrightarrow{\beta_1} & V(\delta) \\
\downarrow{\beta_2} & & \downarrow{\delta_1} \\
V(\delta-2) & \xrightarrow{\delta_2} & V(\delta-1)
\end{array} \]
The triangle in the right hand side will be better suited for our purpose as we will see in the following steps.

**STEP 1.** We shall first construct a morphism \( \beta : V^{(d)} \longrightarrow V^{(d-2)} \) together with a diagram (6.2.1), and with the following conditions:

- There is an element \( h_{\ell}W^\ell \in \mathcal{G} \) so that \( h_{\ell} \) is a monic polynomial on \( z \) of degree \( \ell \), say
  \[
  h_{\ell}(z) = z^\ell + c_1z^{\ell-1} + \cdots + c_\ell \in \mathcal{O}_{V^{(d-1)}, \beta_1(x)}[z],
  \]
  where \( z \) is a global section, so that \( \{dz\} \) is a basis of the module of \( \beta_1 \)-differentials.

Denote by \( \mathcal{R}_{\mathcal{G}, \beta_1} \subset \mathcal{O}_{V^{(d-1)}}[W] \) the elimination algebra corresponding to \( \beta_1 \). This is a simple algebra at \( \beta_1(x) \in \text{Sing}(\mathcal{R}_{\mathcal{G}, \beta_1}) \). We know that \( \tau_{\mathcal{R}_{\mathcal{G}, \beta_1}, \beta_1(x)} \geq 1 \), since \( \tau_{\mathcal{G},x} \geq 2 \), as was previously indicated. Therefore:

* There is an element \( g_mW^m \in \mathcal{R}_{\mathcal{G}, \beta_1} \) so that \( g_m \) is a monic polynomial of degree \( m \), say
  \[
  g_m(z_2) = z_2^m + b_1z_2^{m-1} + \cdots + b_m \in \mathcal{O}_{V^{(d-2)}, \beta_2(x)}[z_2],
  \]
  where \( z_2 \) is a global section and \( \{dz_2\} \) is a basis of the module of \( \beta_2 \)-differentials. Hence \( \{dz, dz_2\} \) is a basis of the module of \( \beta \)-differentials.

**STEP 2.** Here we will address the construction of a smooth scheme \( V_2^{(d-1)} \), together with morphisms \( V^{(d)} \xrightarrow{\delta_1} V_2^{(d-1)} \) and \( V_2^{(d-1)} \xrightarrow{\delta_2} V^{(d-2)} \), so as to complete the diagram (6.4.2). The functions \( f_n(z_1) \) and \( g_m(z_2) \), with the conditions specified in Proposition 6.3 will arise from the construction of the right-hand side in (6.4.2).

Step 1 provides us with an element \( g_m(z_2)W^m \in \mathcal{R}_{\mathcal{G}, \beta_1} \). Via the natural inclusion \( \mathcal{R}_{\mathcal{G}, \beta_1} \subset \mathcal{G} \) (see Proposition 2.16 (1)), the element \( g_m(z_2)W^m \in \mathcal{G} \). The smooth scheme \( V_2^{(d-1)} \) will be constructed below so as to dominate \( V^{(d-2)} \) and so that \( z_2 \notin \mathcal{O}_{V^{(d-1)}} \). Moreover a smooth morphism \( \delta_1 : V^{(d)} \longrightarrow V_2^{(d-1)} \) will be constructed with the condition that \( g_m(z_2) \in \mathcal{O}_{V_2^{(d-1)}}[z_2] \),ur that \( z_2 \) defines a section for \( \delta_1 \). Here \( \{dz_2\} \) will be a basis for the module of \( \delta_1 \)-differentials.

As \( \tau_{\mathcal{G},x} \geq 2 \), we know that \( \tau_{\mathcal{R}_{\mathcal{G}, \beta_1}, \beta_1(x)} \geq 1 \) ([4, Theorem 6.4]). This ensures the existence of

** an element \( f_nW^n \in \mathcal{R}_{\mathcal{G}, \delta_1} \) which is a monic polynomial, i.e.,
  \[
  f_n(z_1) = z_1^n + a_1z_1^{n-1} + \cdots + a_n \in \mathcal{O}_{V^{(d-2)}, \beta_1}(z_1),
  \]
  where again \( z_1 \) is a global section so that \( \{dz_1\} \) is a basis of \( \Omega_{\beta_1}^1 \); and hence \( \{dz_1, dz_2\} \) defines a basis of \( \Omega_{\beta}^1 \).

Finally check that if we succeed in the development of the previous steps, then \( f_n(z_1) \) and \( g_m(z_2) \) will fulfill the condition of the Proposition 6.3.

**Proof.** Here we construct (6.4.2) with the previously required conditions. Étale topology will be used throughout this proof, so let us specify some well-known properties of étale maps.

Fix a smooth scheme \( V \) and suppose given a scheme \( W \) and a smooth morphism:

\[
\begin{array}{ccc}
V & \xrightarrow{\gamma} & W \\
\end{array}
\]
This setting is preserved in étale topology when an étale map $W' \xrightarrow{e} W$ is considered. In fact, a commutative diagram arises by taking fiber products:

$$
\begin{array}{c}
V' \\
\downarrow \gamma' \\
W'
\end{array} \xrightarrow{e} \begin{array}{c}
V \\
\downarrow \gamma \\
W
\end{array}
$$

where $V' \xrightarrow{e} V$ is an étale map, and $V' \xrightarrow{\gamma'} W'$ is smooth. This says that the construction of a scheme $W$ and a smooth morphism $\gamma$ is preserved in étale topology, but only when lifting étale maps in the previous sense (from down-up). This will be the key point for the construction of the schemes and morphisms previously mentioned. Recall our general strategy:

**STEP 1.** First construct the left hand side of (6.4.2), namely the smooth schemes $V_1^{(d-1)}$, $V^{(d-2)}$ and the morphisms $\beta_1$ and $\beta_2$ with the required conditions.

**STEP 2.** Once the previous data is fixed, complete the diagram (6.4.2) (the right hand side) in such a way that the polynomials $f_n(z_1)$ and $g_m(z_2)$ can be chosen as in Proposition 6.3.

1) By assumption $\tau_{G,x} \geq 2(\geq 1)$, so one can find a regular system of parameters $\{x_1, \ldots, x_d\}$ at $O_{V^{(d)},x}$, and an element $h_\ell W^\ell \in G$ so that $h_\ell |_{x_1=\cdots=x_{d-1}=0} = u \cdot x_\ell$ for some unit $u \in O_{V^{(d)}/\langle x_1, \ldots, x_{d-1} \rangle}$.

Consider the smooth morphism

$$
V^{(d)} \xrightarrow{h_\ell} \mathbb{A}_k^{(d-1)} = \text{Spec}(k[X_1, \ldots, X_{d-1}])
$$

defined by $X_i \mapsto x_i$ for $i = 1, \ldots, d-1$. Let $(B, N)$ be the henselization of the local ring $k[X_1, \ldots, X_{d-1}]_{\langle X_1, \ldots, X_{d-1} \rangle}$. This defines $\text{Spec}(B) \xrightarrow{h_\ell} \mathbb{A}_k^{(d-1)}$. Up to multiplication by a unit, the element $h_\ell$ is a monic polynomial of degree $\ell$, i.e.,

$$
h_\ell(z) = z^\ell + c_1 z^{\ell-1} + \cdots + c_\ell \in B[z].
$$

Now replace $A_k^{(d-1)}$ by a suitable étale neighborhood $V_1^{(d-1)}$ where all the coefficients $c_i$ are global sections. Define $\beta_1$ by taking the fiber product. We abuse the notation and set $\beta_1 : V^{(d)} \xrightarrow{h_\ell} V_1^{(d-1)}$.

Let $R\mathcal{G},\beta_1$ denote the elimination algebra with respect to $\beta_1$. Since $\tau_{G,x} \geq 2$, then again $\tau_{R\mathcal{G},\beta_1,\beta_1(x)} \geq 1$ and we repeat the previous argument to define a scheme, say $V^{(d-2)}$, together with a smooth morphism $\beta_2$, so that, a given element $g_m W^m \in R_{\mathcal{G},\beta_1}$ of order $m$ can be expressed as a monic polynomial

$$
g_m(z_2) = z_2^m + b_1 z_2^{m-1} + \cdots + b_m \in O_{V^{(d-2)}}[z_2].
$$

This construction might force us to replace the previous scheme $V_1^{(d-1)}$ by an étale neighborhood, in particular, $V^{(d)}$ is replaced by an étale neighborhood. Set $\beta = \beta_2 \circ \beta_1$.

2) Fix a regular system of parameters $\{x_1, \ldots, x_{d-2}\}$ at $O_{V^{(d-2)},\beta(x)}$. It extends to $\{x_1, \ldots, x_{d-2}, z, z_2\}$ which is a regular system of parameters at $O_{V^{(d)},x}$. Set $\mathbb{A} = \text{Spec}(k[T])$. We now define a smooth
morphism:

\[
V'(d) \xrightarrow{\delta'_1} V'(d-2) \times \mathbb{A}^1
\]

with the condition that \( pr_1 \circ \delta'_1 \) yields \( \beta = \beta_2 \circ \beta_1 \); here \( pr_1 \) is the projection in the first coordinate.

The map \( \delta'_1 \) is uniquely determined if \( T \) is identified with the element \( z \). Note that \( \mathcal{O}_{V'(d-2)} \subset \mathcal{O}_{V'(d-2) \times \mathbb{A}^1} \) and hence \( g_m(z_2) \in \mathcal{O}_{V'(d-2) \times \mathbb{A}^1}[z_2] \). Moreover, check that \( z_2 \) is a global section so that \( \{d_{z_2}\} \) defines a basis of \( \Omega_{\mathbb{A}^1} \).

Let \( \mathcal{H} := \mathcal{R}_{G, \delta'_1} \subset \mathcal{O}_{V'(d-2) \times \mathbb{A}^1} \) and \( \mathcal{H} \) denotes the elimination algebra with respect to \( \delta'_1 \). Again, since \( \tau_{G,x} \geq 2 \), then \( \tau_{\mathcal{H}, \delta'_1(x)} \geq 1 \). The same arguments used before ensures that there are:

- an \( \mathcal{\acute{e}} \)tale neighborhood of \( V'(d-2) \), say \( V'(d-2) \),
- a smooth morphism \( V_2(d-1) \xrightarrow{\delta_2} V'(d-2) \) (here \( V_2(d-1) \) is an \( \mathcal{\acute{e}} \)tale neighborhood of \( V'(d-2) \times \mathbb{A}^1 \)), and
- an element \( f_nW^n \in \mathcal{H} \subset G \) which can be expressed as

\[
f_n(z_1) = z_1^n + a_1 z_1^{n-1} + \cdots + a_n \in \mathcal{O}_{V'(d-2)}[z_1],
\]

with the required properties.

This settles the construction of diagram (6.4.2), and the two polynomials \( f_n(z_1) \) and \( g_m(z_2) \) fulfill the conditions of Proposition 6.3.

**Definition 6.5.** Fix a Rees algebra \( G \) so that \( \tau_{G,x} \geq 2 \) at any closed point \( x \in Sing(G) \), and a simplified presentation, say \( sP = sP(\beta, z_1, z_2, f_{n_1}(z_1), f_{n_2}(z_2)) \), as in (6.4.1). The **slope of \( G \) relative to \( sP \) at a point \( y \in V'(d-2) \)** is defined as

\[
Sl(sP)(y) := \min_{1 \leq j_1 \leq n_1} \left\{ \frac{\nu_y(a_{j_1})}{j_1}, \frac{\nu_y(b_{j_2})}{j_2}, \text{ord}(\mathcal{R}_{G, \beta})(y) \right\}.
\]

Here \( \nu_y \) denotes the order at the regular local ring \( \mathcal{O}_{V'(d-2), y} \) and \( \text{ord}(\mathcal{R}_{G, \beta}) \) is the order function the Rees algebra \( \mathcal{R}_{G, \beta} \) as defined in (2.19.1).

**Definition 6.6.** Let \( G \) be a Rees algebra, so that \( \tau_{G,x} \geq 2 \) for all \( x \in Sing(G) \). A simplified presentation \( sP = sP(\beta, z_1, z_2, f_{n_1}(z_1), f_{n_2}(z_2)) \) is said to be in **normal form at \( y \in V'(d-2) \)** if one of the following conditions hold:

- Either \( Sl(sP)(y) = \text{ord}(\mathcal{R}_{G, \beta})(y) \),
- or \( Sl(sP)(y) = Sl(f_{n_1}(z_1)W^{n_1})(y) < \text{ord}(\mathcal{R}_{G, \beta})(y) \) and \( w^{-\infty}_{y}(f_{n_1}(z_1)) \) is not an \( n_1 \)-th power,
- or \( Sl(sP)(y) = Sl(f_{n_2}(z_2)W^{n_2})(y) < \text{ord}(\mathcal{R}_{G, \beta})(y) \) and \( w^{-\infty}_{y}(f_{n_2}(z_2)) \) is not an \( n_2 \)-th power.

It will be shown in Theorem 6.12 that the rational number \( Sl(sP)(y) \) is entirely determined by the weak equivalence class of \( G \), whenever \( sP \) is in normal form at \( y \in \beta(Sing(G)) \). This will lead to the definition of an H-function along points of \( Sing(G) \).

**6.7. The general case \( \tau \geq e \).**

We address here the case \( \tau \geq e \), now for arbitrary \( e \). It parallels the previous results for \( e = 2 \), and generalized, to some extend, the Weierstrass Preparation Theorem.

**Theorem 6.8.** Let \( G \) be a Rees algebra so that \( \tau_{G,x} \geq e \) at a closed point \( x \in Sing(G) \). Then, at a suitable \( \mathcal{\acute{e}} \)tale neighborhood of \( x \), a transversal morphism, say \( V^{(d)} \xrightarrow{\beta} V^{(d-e)} \), can be defined together with:
Global functions $z_1, \ldots, z_e$, and \{dz_1, \ldots, dz_e\} is a basis of $\Omega^1_\beta$ (module of $\beta$-relative differentials),

- integers $n_1, \ldots, n_e \in \mathbb{Z}_{>0}$, and
- elements $f_{n_1}W^{n_1}, \ldots, f_{n_e}W^{n_e} \in \mathcal{G}$, where

\[
\begin{align*}
  f_{n_1}(z_1) &= z_1^{n_1} + a_1^{(1)}z_1^{n_1-1} + \cdots + a_{n_1}^{(1)} \in \mathcal{O}_{V(d-e)}[z_1], \\
  &\vdots \\
  f_{n_e}(z_e) &= z_e^{n_e} + a_1^{(e)}z_e^{n_e-1} + \cdots + a_{n_e}^{(e)} \in \mathcal{O}_{V(d-e)}[z_e],
\end{align*}
\]

(6.8.1)

(for some $a_i^{(j)}$ global functions on $V(d-e)$). Moreover, the previous data can be defined with the condition that $\mathcal{G}$ has the same integral closure as

\[
\begin{align*}
  \mathcal{O}_{V(d)}[f_{n_1}(z_1)W^{n_1}, \Delta^j_i(f_{n_i}(z_i))W^{n_i-j_i}]_{1 \leq j_i \leq n_i-1, \ i=1, \ldots, e} \oplus \beta^*(\mathcal{R}_\mathcal{G}, \beta).
\end{align*}
\]

Here, $\mathcal{R}_\mathcal{G}, \beta \subset \mathcal{O}_{V(d-e)}[W]$ is the elimination algebra defined in terms of $\beta$ as in Proposition 2.16 and $\Delta^j_i$ are as in Remark 5.3.

**Proof.** The proof follows from a natural extension of the arguments in the proof of Proposition 6.3.

**Definition 6.9.** (Simplified presentations). Let the setting be as in Theorem 6.8. The data

\[
\begin{align*}
  s\mathcal{P}(\beta, z_1, \ldots, z_e, f_{n_1}(z_1), \ldots, f_{n_e}(z_e))
\end{align*}
\]

which fulfills the conditions of Theorem 6.8 is said to be a simplified presentation.

The following Definitions extend those in [6.3] and [6.6].

**Definition 6.10.** Let $\mathcal{G}$ be a differential Rees algebra $\mathcal{G}$ so that $\tau_{\mathcal{G}, x} \geq e$ at a closed point $x \in \text{Sing}(\mathcal{G})$. Fix, at a neighborhood of $x$, a simplified presentation, say $s\mathcal{P} = s\mathcal{P}(\beta, z_1, \ldots, z_e, f_{n_1}(z_1), \ldots, f_{n_e}(z_e))$, as in (6.9.1). The slope of $\mathcal{G}$ relative to $s\mathcal{P}$ at a point $y \in V(d-e)$ is the rational number defined as

\[
\begin{align*}
  S_l(s\mathcal{P})(y) &= \min \left\{ \frac{\nu_y(a_i^{(j)})}{j_i} \right\}, \text{ord}(\mathcal{R}_\mathcal{G}, \beta)(y) \right\}.
\end{align*}
\]

(6.10.1)

**Definition 6.11.** Let $\mathcal{G}$ be a differential Rees algebra in the conditions of the previous definition. A simplified presentation $s\mathcal{P} = s\mathcal{P}(\beta, z_i, f_{n_i}(z_i))_{1 \leq i \leq e}$ is said to be in normal form at $y \in V(d-e)$ if one of the following conditions holds:

- Either $S_l(s\mathcal{P})(y) = \text{ord}(\mathcal{R}_\mathcal{G}, \beta)(y)$,
- or for some index $1 \leq i \leq e$, $S_l(s\mathcal{P})(y) = S_l(f_{n_i}(z_i)W^{n_i})(y) < \text{ord}(\mathcal{R}_\mathcal{G}, \beta)(y)$ and $w_{\text{in}}(f_{n_i}(z_i))$ is not an $n_i$-th power.

The next theorem will show that given a simplified presentation $s\mathcal{P}$ in normal form at $y \in \beta(\text{Sing}(\mathcal{G}))$, the rational value $S_l(s\mathcal{P})(y)$ is an invariant (independent of the presentation).

**Theorem 6.12.** Let $\mathcal{G}$ be a $\beta$-differential Rees algebra (e.g. a differential Rees algebra) with the property that $\tau_{\mathcal{G}, x} \geq e$ along closed point in $\text{Sing}(\mathcal{G})$. Fix a point $x \in \text{Sing}(\mathcal{G})$ and assume that there is a simplified presentation $s\mathcal{P}$ which is in normal form at $\beta(x)$ (see Definition 6.11).

1. The rational number $q = S_l(s\mathcal{P})(\beta(x))$ in (6.10.1) is entirely determined by the weak equivalence class of $\mathcal{G}$.
2. $\mathcal{G}$ and $\mathcal{O}_{V(d)}[f_{n_1}W^{n_1}, \ldots, f_{n_e}W^{n_e}] \oplus \beta^*(\mathcal{R}_\mathcal{G}, \beta)$ are weakly equivalent.

**Proof.** (1) The proof is similar to that of Theorem 5.11 considering now, in Stage B, blow-ups at centers of codimension $e+1$ instead of codimension 2.
monic polynomials. An example of this fact arises already in Theorem 6.8. Moreover, the elimination algebras which appear in our discussions are defined in terms of these polynomials and the elimination algebra which we will indicate below.

Fix a $d$-dimensional scheme $V^{(d)}$ smooth over a perfect field $k$ together with a differential Rees algebra, say $G$, over $V^{(d)}$. Fix a transversal projection $V^{(d)} \xrightarrow{\beta} V^{(d-1)}$. As $G$ is a differential algebra, it is also a $\beta$-differential algebra (see 2.15). In this case, we will indicate that locally at any point $x \in \text{Sing}(G)$, the $\beta$-differential structure of $G$ will allow us to consider a simplified presentation $sP$ with integers of the form: $n_1 = p^{\ell_1} \leq n_2 = p^{\ell_2} \leq \cdots \leq n_e = p^{\ell_e}$, where $p$ denotes the characteristic of $k$. This particular simplified presentations will be called $p$-presentations and will be denoted by

\begin{equation}
(7.1.1)
P = pP(\beta, z, f_{\rho^i}(z)) = z^{p^{\ell_i}} + a_1^{(1)} z^{p^{\ell_i-1}} + \cdots + a_{\rho^i}, 1 \leq i \leq e.
\end{equation}

The exponents $\ell_1 \leq \ell_2 \leq \cdots \leq \ell_e$ are closely related with invariants studied by Hironaka in [32], and also related with other invariants introduced by Kawano and Matsuki in [36], [37], [38].

The notion of $p$-presentations was introduced in [4] for the case $e = 1$. They were denoted by

\begin{equation}
P = pP(\beta : V^{(d)} \longrightarrow V^{(d-1)}, z, f_{\rho^i}(z) = z^{p^{\ell_i}} + a_1 z^{p^{\ell_i-1}} + \cdots + a_{\rho^i}),
\end{equation}

and it was shown there that:

(1) given $x \in \text{Sing}(G)$, the $p$-presentation can be modified into a new $p$-presentation which is in normal form at $\beta(x)$ (see Definition 5.8),

(2) and the value of the H-function is given by

\begin{equation}
(7.1.2)\quad \text{H-ord}^{(d-1)}(G)(x) = \min \left\{ \frac{\nu_{\beta(x)}(a_{\rho^i})}{p^\ell}, \text{ord}(R_{G, \beta})(\beta(x)) \right\},
\end{equation}

where the right hand side is defined in terms of a $p$-presentation $pP = pP(\beta, z, f_{\rho^i}(z))$ in normal form at $\beta(x)$ (see [6] Theorem 4.6. and Corollary A.9).
This simplifies the expression in (5.13.1), as only the coefficient $a_{p^i}$ appears in this formulation. Surprisingly, the contribution of the intermediate coefficients of $f_{p^i}(z) = z^{p^i} + a_1z^{p^i-1} + \cdots + a_{p^i}$ is somehow encoded in the elimination algebra $R_{\mathcal{G},\beta}$.

The previous two properties extend easily to the general case $\tau \geq \epsilon$, via Theorem 6.8 together with presentations as in (7.1.1). Namely:

1. Given $x \in \text{Sing}(\mathcal{G})$, the $p$-presentation $pP$ in (7.1.1) can be modified into another $p$-presentation, which is in normal form at $\beta(x)$. Let us emphasize here that $p$-presentations are particular forms of simplified presentations.
2. Assume now that $pP$ is in normal form at $\beta(x)$, then

$$
(7.1.3) \quad \text{H-ord}^{(d-e)}(\mathcal{G})(x) = \min_{1 \leq j \leq e} \left\{ \frac{\nu_{\beta(x)} a_{\ell j}}{p^j} \right\} \text{ord}(R_{\mathcal{G},\beta})(\beta(x)).
$$

### 7.2. $p$-presentations and monoidal transformations.

Insofar $\mathcal{G}$ was assumed to be a differential Rees algebra. It is in this context in which Theorem 6.8 applies; namely, the theorem ensures that simplified presentations exists for these Rees algebras.

A natural notion of transformation of a $p$-presentation was studied for the case $e = 1$ in [6]. There, given a $p$-presentation of $\mathcal{G}$ over $V(d)$, say $pP = pP(\beta, z, f_{p^i})$, a new $p$-presentation, say $pP_1 = pP_1(\beta, z_1, f_{p^i}^{(1)})$, is defined in terms of $pP$ and of the monoidal transformation. This is denoted by

$$
\begin{array}{ccc}
pP & \xrightarrow{V(d)} & pP_1 \\
V(d) & \quad & V_1(d)
\end{array}
$$

The simplified presentations given by Theorem 6.8 enables us to extend the previous discussion to the case $\tau \geq \epsilon$ for presentations in the setting of (7.1.1). In other words, the previous discussion applies for a presentation once we fix a sequence of transformations (2.17.2). This will enable us to attach a simplified presentation to $\mathcal{G}$, locally at $x \in \text{Sing}(\mathcal{G})$, in terms of $\beta_r$, and this will be achieved by successive “transformations”.

The result in Theorem 6.12 has now a natural formulation for the $\beta_r$-differential Rees algebra $\mathcal{G}_r$ in (2.17.2). In addition Definition 6.13 can also be stated for $\mathcal{G}_r$. Consequently the $d-e$-dimensional H-function of $\mathcal{G}_r$, say

$$
\text{H-ord}^{(d-e)}(\mathcal{G}_r) : \text{Sing}(\mathcal{G}_r) \longrightarrow \mathbb{Q}_{\geq 0},
$$

can be defined, and again Theorem 6.12 applies to ensure that the function is intrinsic.

### 7.3. On tamed H-functions and the proof of Theorem 2.27

We address here the proof of Theorem 2.27. Firstly we will introduce the notion of strong monomial case in Definition 7.4 which will encode the numerical conditions in (2.27.1). Once this point is settled, the statement of Theorem 2.27 will be reformulated in Theorem 7.6.

As a first step, recall the construction of the monomial algebra introduced in (2.25.1), where a monomial algebra, say

$$
(7.3.1) \quad \mathcal{M}_r W_s = \mathcal{O}_{V_r^{(d-e)}}[I(H_1)^{h_1} \ldots I(H_r)^{h_r} W_s],
$$

is assigned to any sequence (2.17.2), by setting, for $i = 0, \ldots, r - 1$:

$$
(7.3.2) \quad \frac{h_{i+1}}{s} = \text{H-ord}^{(d-e)}(\mathcal{G}_i)(\xi_Y) - 1,
$$

and where $\xi_Y$ denotes the generic point of $Y_i$, the center of the monoidal transformation.

**Definition 7.4.** Let $\mathcal{G}$ be a Rees algebra so that $\tau_\mathcal{G}(x) \geq \epsilon$ at any closed point $x \in \text{Sing}(\mathcal{G})$. Let the setting be as in (2.17) and assume that (2.17.2) is defined so that the elimination algebra of $\mathcal{G}_r$
is monomial in the sense of (2.23.1). The Rees algebra \( G_r \) is said to be in the strong monomial case if at any closed point \( x \in \operatorname{Sing}(G_r) \):

\[
(7.4.1) \quad \text{H-ord}^{(d-e)}(G_r)(x) = \text{ord}(M_r W^s)(x).
\]

**Remark 7.5.** In [8, Theorem 8.5 and Remark 8.6] it is proved that the condition \( \text{ord}(M_r W^s)(x) = \text{H-ord}^{(d-1)}(G_r)(x) \) holds if and only if \( M_r W^s = (R_{G_r},r) \), and this ensures the existence of a hypersurface of maximal contact locally at the point (case \( e = 1 \)). The extension of this fact to the general case is straightforward.

**Theorem 7.6.** Let the setting be as in Definition (2.2.1). Assume that \( G_r \) is in the strong monomial case at any closed point \( x \in \operatorname{Sing}(G_r) \). Then any combinatorial resolution of \( M_r W^s \) can be lifted to a sequence of monoidal transformations over \( G_r \), say

\[
(7.6.1) \quad G = G_1 \cdots G_r \cdots G_N
\]

which is either a resolution of \( G \) (i.e., \( \operatorname{Sing}(G) = \emptyset \)), or \( \tau_{G_r}(x) \geq e + 1 \) at any closed point \( x \in \operatorname{Sing}(G_N) \) (improvement of the \( \tau \)-invariant).

**Proof.** We are considering here the situation where \( \tau_{G_r,x} \geq e \) for all closed point \( x \in \operatorname{Sing}(G_r) \), and we are going to study the closed points \( x \) where \( \tau_{G_r,x} = e \). Our proof will strongly rely on the existence of \( p \)-presentations (see (7.1), say \( sP = sP(\beta, z_i, f_{p\ell_i}(z_i)) = z_i^p + a_{1i} z_i^{p_1} + \cdots + a_{e\ell_i} z_i^{p_{e\ell_i}} \)) which we may assume, in addition, that are in normal form at \( \beta(x) \in \operatorname{Sing}(G_r) \).

Firstly assume, as we previously indicated, that the elimination algebra of \( G_r \) is monomial. Namely, that

\[
(7.6.2) \quad (R_{G_r},r) = \mathcal{O}_{\mathcal{V}^{(d-e)}}[I(H_1)^{\alpha_1} \cdots I(H_r)^{\alpha_r} W^s].
\]

The monomial algebra \( M_r W^s \) in (7.3.1) relates to the \( p \)-presentation in the following manner:

- \( a_{j_i}^{(i)} W^{j_i} \in M_r W^s \) for \( j_i = 1, \ldots, p_{\ell_i}, i = 1, \ldots, e \). Meaning that the coefficients \( a_{j_i}^{(i)} W^{j_i} \) are in the integral closure of \( M_r W^s \). We express this fact by saying that \( M_r W^s \) divides the coefficients.
- \( M_r W^s \) divides the elimination algebra \( (R_{G_r},r) \) in (7.6.2) (i.e., \( h_i \leq \alpha_i \) for \( i = 1, \ldots, r \)). This fact is guaranteed by (7.3.2) and (7.13), together with the law of transformations for Rees algebras.

Let us address now the numerical conditions defined in terms of the H-functions \( \text{H-ord}^{(d-e)} \) at points of \( \operatorname{Sing}(G_r) \). Firstly recall the formulation of the H-function in (7.1.3) which relies only on the elimination algebra or on the constant terms of the \( e \) polynomials, say \( a_{j_i}^{(i)} \).

(A) Assume that \( \text{H-ord}^{(d-e)}(G_r)(x) = \text{ord}((R_{G_r},r)(\beta_r(x))) \) at \( x \in \operatorname{Sing}(G_r) \). In this case, Remark (7.5) says that \( M_r W^s = (R_{G_r},r) \), this, in turn, ensures that all coefficients \( a_{j_i}^{(i)} W^{j_i} \in (R_{G_r},r) \). These conditions, together with the fact that \( f_{p\ell_i}(z_i) W^{p\ell_i} \in G_r \), say that, up to integral closure, \( z_i W^{p\ell_i} \in G_r \) for \( i = 1, \ldots, e \). In particular, this guarantees that \( z_1 = \cdots = z_e = 0 \) has maximal contact with \( G_r \) at \( x \), and hence in an open neighborhood of \( x \). Therefore, at a neighborhood of \( x \) the Theorem can be dealt with as in the case of characteristic zero.

(B) Assume that \( \text{H-ord}^{(d-e)}(G_r)(x) < \text{ord}((R_{G_r},r)(\beta_r(x))) \) at \( x \in \operatorname{Sing}(G_r) \). Then, there is an index \( j \) for which \( \text{H-ord}^{(d-e)}(G_r)(x) = \frac{\nu_{\beta_r(x)}(a_{j_i}^{(i)})}{p_{j_i}^{\ell_i}} \) (\( = \text{ord}(M_r W^s)(x) \)). This equality shows that

\[
a_{j_i}^{(i)} W^{p_{j_i}} = M_r W^s,
\]
meaning that both algebras have the same integral closure. This ensures that, up to multiplication by a unit, \( a^{(j)}_{p^j} \) can be taken as a monomial.

Fix now a smooth permissible center \( C \) with generic point \( y \), so that \( x \in C \). A property of \( p \)-presentations is that they can be chosen so as to be in normal form simultaneously at \( x \) and \( y \) (see \[6, Proposition 5.8\]). We now compute \( H \text{-ord}^{(d-e)}(G_r)(y) \). We claim that

\[
H \text{-ord}^{(d-e)}(G_r)(y) = \frac{\nu_{\beta_r(y)}(a^{(j)}_{p^j})}{p^j}
\]

for the same index \( j \) we have taken before. In fact, \( \text{ord}(M_r W^*)(y) = \frac{\nu_{\beta_r(y)}(a^{(j)}_{p^j})}{p^j} \), and since all coefficients and the elimination algebra are divisible by \( M_r W^* \), then

\[
H \text{-ord}^{(d-e)}(G)(y) = \min_{1 \leq j \leq e} \left\{ \frac{\nu_{\beta_r(y)}(a^{(j)}_{p^j})}{p^j}, \text{ord}((R_{G,\beta})_r)(\beta_r(x)) \right\} = \frac{\nu_{\beta_r(y)}(a^{(j)}_{p^j})}{p^j}
\]

Summarizing, there is a particular index \( j \) with the following properties:

- \( j \) provides the value of the \( H \)-function at \( x \) and at \( y \). Namely,

\[
H \text{-ord}^{(d-e)}(G)(x) = \frac{\nu_{\beta_r(x)}(a^{(j)}_{p^j})}{p^j} \quad \text{and} \quad H \text{-ord}^{(d-e)}(G)(y) = \frac{\nu_{\beta_r(y)}(a^{(j)}_{p^j})}{p^j}
\]

- the role of this \( j \) is stable under transformations.

In this way, Theorem \[6,8\] reduces the proof of this theorem to the case of only one index say \( j \), which leads us to consider the algebra

\[
G_r = O_{(V_j^0, [f_{p^j} (z)]W^{p^j}, \Delta^{p^j - 1}(f_{p^j} (z))]W^{p^j - 1}]_{1 \leq i \leq p^j - 1} \odot (R_{G,\beta})_r.
\]

Recall that we assumed that \( \tau_{G_r, x} = e \). The theorem of elimination of variables together with the previous discussion ensure that \( \tau_{G_r, x} = 1 \); and moreover that \( G' \) is in the strong monomial case. This is the setting in which \[6, Theorem 8.14\] applies; this last theorem is the particular case of Theorem \[7,9\] which applies for Rees algebras with \( \tau \)-invariant equal to 1. It ensures that after a sequence of \( N - r \) transformations, the final algebra \( G'_N \) is resolved, or \( G'_{N, x'} \geq 2 \) for all \( x' \in \text{Sing}(G'_N) \). This sequence of transformations is permissible for \( G_r \). Moreover, it will guarantee that either \( G'_N \) is resolved, or \( \tau_{G'_N, x''} \geq e + 1 \) for all \( x'' \in \text{Sing}(G'_N) \).

### 7.7. Application to embedded resolution of 2-dimensional schemes.

The embedded resolution of surfaces treated in \[7\] for the hypersurfaces case, can now be extended to prove embedded desingularization of arbitrary 2-dimensional schemes (over perfect fields). This provides a desingularization of 2-dimensional schemes \textit{a la Hironaka}, namely by applying successive monoidal transformations along the highest Hilbert-Samuel stratum.

**Theorem 7.8.** Given a reduced 2-dimensional scheme \( X \) over a perfect field, there is a sequence of monoidal transformations

\[
X \xrightarrow{\pi_{C_1}} X_1 \xrightarrow{\pi_{C_2}} \cdots \xrightarrow{\pi_{C_n}} X_n,
\]

where each center of the blow-up \( C_i \) is so that \( C_i \subset \text{Max} HS_{X_i} \) (here \( \text{Max} HS_{X_i} \) denotes the maximum Hilbert-Samuel stratum of \( X_i \)), such that

i) \( X_n \) is a smooth embedded desingularization of \( X \), which modifies only the singular points of \( X \).

ii) The exceptional locus of the composition map \( X \xleftarrow{\pi} X_n \) has only simple normal crossings.
Idea of the proof.

(1) Consider an embedding of $X$ in a smooth $d$-dimensional scheme, say $X \subset V^{(d)}$. In this setting, Hironaka attaches to the maximum Hilbert-Samuel stratum, say $\text{Max} H S_X$, an algebra $G$.
(2) As $X$ is a 2-dimensional scheme, then $\tau_{G,x} \geq d - 2$ at any closed point of $x \in \text{Sing}(G) = \text{Max} H S_X$. See [10] Proposition 11.4.
(3) Our generalized Weierstrass Preparation Theorem in [6,8] and the corresponding H-functions in [6,13] enable us to extend the discussion in [7] Section 4.
